International Conference for Phoenixes on Emerging Current Trends in Engineering and Management

PECTEAM 2K26

on

March 27th & 28th 2026

Organized by

PANIMALAR ENGINEERING COLLEGE

An Autonomous Institution

Approved by AICTE | Affiliated to Anna University | Recognized by UGC
All Eligible UG Programs are Accredited by NBA
Bangalore Trunk Road, Varadharajapuram, Poonamallee, Chennai- 600 123

PREFACE

Dear Distinguished Delegates and Guests,

The organizing committee is extremely privileged to welcome our distinguished delegates and guests to the International Conference for **P**hoenixes on **E**merging **C**urrent **T**rends in **E**ngineering **A**nd **M**anagement (**PECTEAM 2K26**) which will be held from March 27th to 28th, 2026 in Chennai, Tamilnadu, India.

The objective of this conference is to bring together numerous problems encountered in the current as well as future high technologies under a common platform. It has been specifically organized to congregate international researchers and technocrats for presenting their innovative work, share and gain knowledge to have a proper insight into the significant challenges currently being addressed in various fields of Computing and Expert Technology.

The conference proceedings have a complete track record of the papers that are reviewed and presented at the conference. The principle objective is to provide an international scientific forum wherein the participants can mutually exchange their innovative ideas in relevant fields and interact in depth through discussion with peer groups. Both inward research as well as core areas of Computing and Expert Technology and its applications will be covered during these events.

It is guaranteed that a high quality program will be conducted as the conference will be graced by an unparalleled number of professional speakers from multidisciplinary fields, both from India and abroad.

We would like to thank the chief patron, patrons, convenors, organizing committee members, advisory members for their immense help, motivation, constant cooperation and continuous encouragement for the conference. We deeply appreciate the editorial board for their wonderful editorial service for the successful outcome of this proceeding. We are very much grateful to all those who have contributed both in the front desk and backyard to make PECTEAM 2K26 as a grand success.

PECTEAM, featuring high impact presentations, would be enriching and undoubtedly an unique, rewarding and memorable experience being hosted at Panimalar Engineering College, Chennai, INDIA.

Dr. S. MALATHI
Convenor

INDEX

SL.NO	PAPER TITLE & AUTHORS	PAGE NO
1.	Defense GPT – Phishing detection using ML Alwin Infant P , Godwin Arulraj S, Ezhilarasan E	1
2.	Data-Driven Crop Recommendation System Using Machine Learning Mr.Dhankshunhaamoorthy, Dhiviksan K K, Janarthanan R, Giridharan R, HariHaran M	9
3.	IOT Enabled Driver Safety System for Accident Detection and Alcohol-Aware Engine Control Leones Sherwin Vimalraj S, Lydia J, Jocelyn Mary Joyce L, Celestina Edal Qveen S, Afrin Banu A	15
4.	AI-Based Waste Segregation Management Alwin Infant P, Gobinath R, Dilip Kumar B	20
5.	AI-Driven Micro Plastic Pollution Prediction Using Multi-Source Satellite Intelligence Deeban S, Daniel Jacob J, Caalvin Ruban J, Dinesh Babu S, Boobesh AG	26
6.	AgroGuardAI: A Multimodal Deep Learning Framework for Early Detection of Plant Stress and Disease Using Smart Sensor and Vision Integration Rahul Nelogi, Sandeep Reddy, Rohith V, Sagar Gangal, Sachidanand V Koujalgi	32
7.	Crime Arrest Prediction Using Stacking Ensemble Learning. Deepa P, Jayasanjay T, Jaya Sabari R	36
8.	Chain-Of-Hope: Blockchain for Ethical Blood and Organ Matching. Lincy Jemina S, Gautham Sangaraju, Gunji Venkata Krishna Karthik.	43
9.	Self-Balancing Electric Cycle Using Gyroscopic Stabilization and PID Control Shreya M, G.Merlin Suba, Abinaya B, Mirudhula A, Shamini S.	49
10.	AgriSense AI: Machine Learning Approaches for Smart Crop Yield Prediction Elangovan C, Raja Rajeshwari K, Priyadharshini L, Pradeepa R, Ponkeerthiga T. Jennifer.G	54
11.	Face Recognition based Attendance System. Dr.A.Hemlathadhevi, Aderu Chenchu Nikhil, Chakka Rithvik ,Gokul.R.	60
12.	Deep Inspect AI: An Intelligent Machine Learning Framework for Automated Defect Detection in Smart Manufacturing Systems Nithin Katariya V , Nithin K S, Narasimha, Nihar Jh, R Monish Babu	68
13.	PlacentaGuard: A Multi-Modal Deep Learning Frame- work for Temporal Ultrasound Analysis and Early Pre- diction of Placental Dysfunction. Madhivani A, Ms. Shyamala P, Madhumetha M S, Meenakshi A S, Nancy Angel J.	73

14.	Adaptive Patient-Specific Alarm Optimization Using Statistical Modelling for Intelligent ICU Monitoring Systems Varun M, Srinath K, Sudharshan R, Vigneshwar V, Dr. Leelavathy S, Mr Suresh S	80
15.	ADIDAS-D: Autonomous Defence Intruder Detection Aerial System-Drone Damodharan R ,Dhivagar S, Dheeraj Singh R	89
16.	Wireless Charging System for Moving Electric Vehicles Ameelia Roseline A , Shreeram V, Sunil Kumar J, Sujith S	95
17.	SmartQCare: A Real-Time Queue Management System for HealthCare Rekha C , Sasidaran S, Vishalini B, Tanshika JS, Sanjana A	99
18.	Next-Generation AI-Powered Border Security Framework Using Multi-Model Surveillance and Intelligent Threat Detection Mohammed Zain, Sanjana R G, Rahila Mahammed, shafee Sarwan, Nawaz Ahamed	105
19.	Power BI-Integrated Cloud-Edge Architecture for Real-Time Intelligent Data Analytics and Visualization in Distributed Edge Computing Environments Sinchana K Rao, Savitha Gundappa Kurigara, Vaishnavi G P, Shaista Seher M A , Darshani A	110
20.	Explainable AI-Based Financial Market Prediction Using Ensemble Machine Learning and Temporal Data Analytics P N Bhoomika ,Sonia N ,Navnith Krishna G, Rochan R Kulkarni ,K Vengatesan, Sweta Chopdar	114
21.	Arise: Autonomous rover for intelligent sensing and environment monitoring Vasudevan Veeraraghavan, Hariprasath Shanmugasundaram, Gokulakrishnan Mani, Hariharan Rajesh Kannnan	118
22.	Smart agricultural rover for automated crop monitoring and disease detection Ramesh Kumar Chandran, Henry Rajaseelan Suresh kumar, Hariprakash Jayaprakash , Jagadeesan Ponnuswamy	123
23.	Sensor-based smart shoe for safe and independent mobility Ameelia Roseline A , Anusha R, Dharshini V, Asmita Ramakrishnan, Asin A	128
24.	Lightweight CNN for plant disease diagnosis: Providing an instantaneous solution to various plant diseases through the enhanced Plant Village dataset Dr K.Sangeetha, Dr K.Valarmathi, Meenakshi.D, Kavishri. N, Mahadevi.M	135
25.	Pattern-Enhanced Fake News Detection Using Deep Learning: Deployment Through a Chrome Browser Extension and User Experience Evaluation Nithish M , Paul Joshua L,Tamilarasan T	143
26.	Safety-Aware Urban Route Planning Using Risk-Weighted Graph Optimization Prashanth S, S Prashanth, Dr. M. Sangeetha	148
27.	Offline Learning App for Rural Students Ramana R, Priyadharshini K, Pushpalatha J	153

28.	Comparative Finite Element Analysis of Epoxy Resin Reinforced Laminated Composite Plates Using Glass and Basalt with Different Fibre Orientations P Iyyan Paramanandam, J Bharath, D Subramaniam, G Surendar, S Surendar	159
29.	Mechanical and operational characteristics of pneumatic feed drilling machine N. Nithyanandan, Pragadeeswar L, Suresh R, Rahul Ganesh A. U, Subhashanraj P	166
30.	Influence of Stitching on the Impact Resistance of Fiber-Reinforced Epoxy Laminates Mr.R.Harish, Mr.S.Naveen Karthik, Mr.M.Madhan Kumar, Dr.J.Gunasekaran, Mr.J.Murugesan	173
31.	A Review On Flax Fibre Reinforced Polymer Composites Modified with Alumina (Al2o3) Fillers Ganesan Gnanakumar, Caleb K J, Sanjivarajan P A, Sukumar E D, Yuvabalaganesh S	181
32.	Effectiveness of Clay-Based Prosthetic Implants for Amputated Metatarsus: Implications for Gait Restoration and Biocompatibility – A Review B Bradley Bright	191
33.	Hand Gesture Recognition Using Raspberry Pi and Open-CV Mrs. Tamilselvi D, Belintha Dulciyaa A, Bellamkonda Deepana, Amirthavarshini P,Sheeba Santhosh	201
34.	Smart Digital Twin-Based IoT Container Monitoring System for Real-Time 3D Logistics Tracking N. Chidambaram, Sanjay V, Sharan U, Shyam Madav S	210
35.	Transforming Retail Experience Using Indoor Navigation and Smart Assistance Supriya M, Rithika R, Shruthika S, Sureka K, Karthikeyan D, Nithish Narayanan D	216
36.	HBTOA: Hybrid Barnacle-Tortoise Optimization Algorithm for Global Optimization Mrs. D. Padmapriya, S. Saranya, C. Sri Varshini, R. Susmitha, R.S.Thanusri	221
37.	Offline Ensemble Deep Learning Framework for Automated Tomato Leaf Disease Diagnosis Lincy Jemina S, Harikrishnaa S, Gokul E	228
38.	IOT based advance battery monitoring system Parthasarathy A, Mr.Tamilarasan T, Nithesh V	233
39.	Process Optimization and Emission Control in LPG Pipeline Hot Flaring Operations Using Six Sigma Methodology Dr N Venkateswaran	238
40.	Role of Auditor Independence in Ethical Financial Reporting Lakshmi B , Sofia Vincent J , Ilakeya U	246
41.	An Empirical Study On Loan: Portfolio in Financial Service Industry Dr D. Chitra	251

42.	Post Interaction Communication and Niche Talent Retention: A Longitudinal Study Dr.M. Beulah Viji Christiana	256
43.	A Study On the Impact of Movies and Web Series On Socio - Emotional Intelligence On Gen Z in Chennai E. Rajeshwari, T. Rithiga, J. Jerita Esther, V. Vishali, S. Uma Mageshwari, P. Lavina	262
44.	Mechanical characterization and vibration analysis of flax fibre and rice husk reinforced polymer composites: a review S.Santhosh Kumar, M.Guhan, E. Kavimani, K.S.Vignesh, P.Anish	265
45.	Design and Analysis of TEE Joint in FDM 3d Printer Using PLA Material Anbarasu. A, agathiyan A, Anand Raj R,Anthony Francis N, Adhi Kesavan V, Adhi Subramani I	273
46.	Artificial Intelligence in Biomaterials for medical implantation - Comprehensive Review P. Senthil Kumar	280
47.	The Influence of Artificial Intelligence-Based Personalization On Consumer Buying Behaviour in Online Retail Platform Amuthuni.S, Arthi.M, Hanshiga.G.V, Harini.S, Kishanthika.K, Hemalatha.M	287
48.	The Role of Employee Emotions in Building a Positive Workplace Culture Jayasree.k, Ilakiya.p.k, Abinaya.R, Janani.S	292
49.	Smart Multi-Hazard Disaster Alert and Safety System for Modern Homes A Multi-Sensor Based Early Warning and Automatic Safety Response System for Residential Environments Lourdu ferdine .A, Kannagi.S, Libika.S ,	295
50.	Analysis and optimization of car seat frame to increase safety measures Rishi Madhan, Rahul A, Krishnasamy N, Saran M, Naveen K,,	299
51.	Iot-Based Hierarchical Solar Array Monitoring System (HSAMS) of Real-time Panel-Level Fault Detection with ESP32 and INA219 Sensors Mathiyazhagan S , Dharansurendar SS, Rahul M J , Jaya Surya S, Puviyarasan M.,	304
52.	Experimental Analysis made on Hybrid Composite Joint of Woven Ring Type M. Harish, D. Logeshwaran, I. John Solomon, B. Prabhu, B.Shanmuganathan	312
53.	Enhancement of performance and emission characteristics of neat palm biodiesel with enriched hydrogen K.Thiruselvam1, G.Yuvaraj, Yaswanth.U, Surya.R, Sathya Narayanan.V	318
54.	Study on mechanical behaviour of austempered ductile iron for a coupler head during wedm Sharun . V, Paul Theophilus Rajakumar .I, Amos Gamaleal David, Raja Karthikeyan .I	324
55.	Optimization of Process Parameters on TIG Welded AISI 409 Stainless Steel G.Senthilkumar , V.Thamizh Nilavan, M.Kesavan, P.Pozhilan,	330

	Hariharan	
56.	Digital Twin Assisted Monitoring and Optimization of Fused Deposition Modelling (FDM) Additive Manufacturing Process Sujith E , Ramkumar S, Sakthi Kumar P, Devadharshan S, Ashok Kumar K, Puviyarasan M	339
57.	Data-Driven Online Prognostics for Machine Health Monitoring in Digital Manufacturing Avinash, Raghavendra, Blesswin, Raja Karthikeyan K, Puviyarasan M, Karthikeyan L	346
58.	Portable Air Filtration and Pollution Control unit for Urban environments K.R.Padmavathi , Michael Megus M, Siraan Abdul Razack S, Anbumani V, Angnilo Berlins K	353
59.	Intelligent Home Energy system with Ai Energy Assistant C. T. Manikandan , R. Madhan Kumar, P. L. Govardhan, V. Govindan, P. Aravind Tharun	358
60.	Multilingual AI Financial Advisor Thanush C A, Sivanandham R, Sriparthasarathy R, Kiran G, Mr. S. Suresh M.E, Siva S	361
61.	IOT - Enabled Autonomous Robot for Hazard Monitoring and Disaster Response Dr. J. Navarajan, Hariharan G, Gopinath N G, Hariharan S	368
62.	Designing an AI-Enhanced Cybersecurity Curriculum for Criminal Justice Professionals: A Progressive Learning Framework Yuvashri C K, Suruthi A, Thenika R, Sujitha R, Vijayalakshmi S, Vommi Dhanusri	373
63.	Vehicle to vehicle communication using LORA and GPS GSM and firebase technology Prof. S. Deepa, R. Petchimuthu, V. Naveen Kumar, S. Panneerselvam	377
64.	Effects of Social Media On Governance and Public Decision-Making in India Dr.Sindhiya Rebecca.A, Aishwarya.V, Chitra Devi.P, Dhanya A.K, Hemapriya.A.S,	384
65.	An Empirical Study on the Influence of Customer Feedback on Online Purchase Behaviour in the FMCG Sector Dr.A.Elaiyaraja, Harini.S, Harshini.V, Harini S, Brindha.M	387
66.	To Study A Social Media Influencers On Gen Z Purchasing Behavior Pattern Towards Skin Care Products In Chennai City Mirudula, J. Pavithra, C. Ranjana, K. Vijayalakshmi	390
67.	Trust in Trends: Understanding Genz's Reliance On Social Media Influencers Dr Satheesh kumar S, Gayathri V, Krithika S, Gifta Getziah Y, Hemalatha H, Abinayaa R	395
68.	A Study On the Relationship Between Consumer Buying Behaviour and Brand Preference Athira G, Bharathy S, Kaneshka A, Kavya S K	399
69.	"Exploring How User Stickiness And Social Psychological Factors Stimulate (E-Wom) In Fintech Innovation" Jayasree k, Harini j p, Jeevitha k, Jaishree r, Kanchana k	402

70.	Impact of AR and Live Shopping on Gen Z's Video-Based Commerce in Tamil Nadu Ramya E, Sreebagya J, Thanisha Priyanka N V, Naveena R, Vaishnavi R	407
71.	Impact of Artificial Intelligence On Recruitment Process in Chennai It Sector Companies Dr.K.Suresh Kumar , M.Sakthi Poojitha , G.D.Nithya Veni , D.Monisha, M.Mounasudha , Sumaya Farhein,	410
72.	Intelligent Accident Prevention and Alert System Using Sensors and Machine Learning MS.K.KAVITHA , Jayanth Arivazhagan	413
73.	Synthesis and Mechanical Characterization of Aluminium 6061–Graphite Composites via Stir Casting Louies Praveen S,Senthil kumar P,.Saravanan R , V.J.Bharaneedharan, Niwin Solomon W	422
74.	Analysis of performance and emission characteristics of biodiesel using cotton seed oil with cerium oxide nanoparticles K.Thiruselvam, Rishit Bhuvanan B M, Rajasekar D, Vishwa K, Santhosh Kumar M	428
75.	Hybrid Ensemble Learning Framework for Network Intrusion Detection Using Random Forest, Xgboost, And Stacking Classifiers Sivakumar Kaliyappan, Lingeshwar Kudiyarasu, Senthil Kumar Krishnan, Nallathambi Govindasamy	434
76.	The AI Skeleton Key: Bypassing MFA via Automated AiTM Phishing M.Vithunya, T.Varsha, N.Yutika, K.B.Swetha, S.Thamayanthi, & K. Madhumithra.	453
77.	Fake News Detection on Social Media Using Machine Learning Joel Livingston S, Karthikayan R, Hemanth Kumar S Gokula Kannan S V, Hariharan S, Harish B	459
78.	Early Hunger Risk Prediction and Transparent Relief Distribution Using AI and QR Verification Dr K. Sangeetha , Dr K. Valarmathi, Monisha B, Monica S.J.	465
79.	Data Transmission and Detection in TeraHertz Wireless Communication Networks with less Error Rates Premkumar M, Mohamed Sameerudeen MK, Logesh S, Macharla Manoj	473
80.	Smart Air Pocket Detection for Urban Flooding Renitta J , Reshma R, Rithanya S	477
81.	A Study On Impact of Gamification On Employee's Motivation Towards Engagement Dr.Sofia Vincent , R.Venassheni , D.Ragavi , S.Ramya, R.Vidhya, J.Tamil Selvi	481
82.	Viewer Attention and Distraction Behaviour While Watching Movies: A Comparative Study of OTT and Theatre Audience. Dr .K. Suresh kumar, Ragamaliga.J, Pooja.K, Raksha.R, Rithika.S, Sneha.K,	484
83.	A Study On the Impact of Discounts and Promotional Offers On Impulse Buying Behaviour S. Sakthikumar , J. Tamilselvi , G. Mithra , L. Sandhiya , S. Swathi	488
84.	Attitudes of Employees Towards Gender Equality in Educational Institutions	491

	Jenitha G, Hemasri D, Anandhi A, Keerthi Vaheni S, Pavithra N, Christy Jasmine R	
85.	A Study On the Impact of Business Analytics On Improving Hiring Efficiency in IT Companies from a Candidate Perspective Radhiga.R, Archana.R, Jaya Shree.B, Bhavya.G	495
86.	Intelligent Emergency Healthcare and Medicine Tracking System Dr. J. Navarajan , Shalini J, Shahana M U, Subiksha S	499
87.	The Study on The Role of Venture Capital in Fostering Startup Development, Driving Innovation, and Enhancing Entrepreneurial Growth in Emerging Markets Keerthana.M, Karthika.S, Janaki.B, Varsha.T. R	505
88.	UPI Culture: How Digital Payments Influence Student Spending Behaviour Dr. Sofia Vincent J, Reshma Y, Bhargavi S, Kavidharshini K, Baby Raji Roslin A	509
89.	A Study On Occupational Health and Safety Practices Akilan Ramasawmy, Rehoboth Jonathan F, Michael Varun V R, Anish Godshalom	515
90.	Role Of Social Media In Shaping Beauty Perception And Consumer Behaviour Dr.P. Shalini, P. Prithusha, M. Lalitha, Vaishnavi Venugopal, R. Vennila, S. Sowmya Singh	520
91.	Artificial Intelligence-Based Learning Platforms and Student Satisfaction. Evidence from Higher Education Shailayaanee.M, Vijaya Lakshmi. G, Sanjusree. J , Priya.N , Yamuna.M, Nila.M	523
92.	How Firms Act as Political Actors in Global Markets Kola Nikitha , R.T.Kiruthika , B.Abirami , B.Chandrakala , K.Devadharshini,Thanu Sri	528
93.	Design and analysis of hybrid manufacturing of go-kart tires Mr.S.DhanaSekar, Vikram R , Ilaiyarasan M , Sunil P , Santhosh Kumar P	532
94.	Comparative analysis of spur gear drive made of same material and different material Mr. G. Senthilkumar, Kevin Robert. I, Sathish Kannan S, Kishore M, Gokulnath S	539
95.	Design and structural analysis of tractor rear axle using finite element method Antony Nixen Raj A, Infant Aswanth J, Lathishwaran M, Manikandan K	548
96.	A critical review on free vibrational characteristics of natural fibre reinforced polymer composite laminates K.M. Keerthi Ramanaa, J. Jeeva, R. Prasanna, S. Manoj Kumar, R. Murugan, L. Karthikeyan	554
97.	Critical Review on Mechanical Properties of Fiber Reinforced Polymer Composite Laminates made of Synthetic Fibers Aravindhan R, Aravinth Arasu D, Harish Kumar K, Nagaarvinth N, Murugan R, Karthikeyan L	566
98.	A Critical Review on Mechanical Properties of Reinforced Polymer Composite Laminates made of Natural Fibers Hariharan E, Sri Sathuguru Paramathma V, Umapathy V, Sakthivel P, Murugan R, Karthikeyan L	577

99.	A critical review on free vibrational characteristics of synthetic fiber reinforced polymer composite laminates Gokulraj V, Naveen Kumar D, Manoj Kumar M, Kathiravan N, Murugan R, Karthikeyan L	584
100.	Smart Ai For Understanding Nonverbal Communication In Autistic Children Suguna T , Florancea angelin A, GAYATHRI K J, Harini B, Ettikuppam Charmi Sree, Gayathri S	592
101.	Flexiclean: A Mobile-Controlled Smart Cleaning Robot for Efficient and Cost-Effective Automation Dr. Vinmathi M S , Pavithrra Shakthi S A, Ramya P	596
102.	Before The Beat Stops: Ai-Driven Cardiac Arrest Prediction Ameelia Roseline A , Gayathri K, Desiga L, Anusha G, Deepa Rani.M ,Aswini.A	601
103.	IOT Enabled Driver Safety System for Accident Detection and Alcohol-Aware Engine Control Leones Sherwin Vimalraj S, Lydia J, Jocelyn Mary Joyce L Celestina Edal Qveen S, Afrin Banu A	615
104.	Hybrid Ensemble Learning Framework for Network Intrusion Detection Using Random Forest, Xgboost, And Stacking Classifiers Sivakumar Kaliyappan, Lingeshwar Kudiyarasu, Senthil Kumar Krishnan, Nallathambi Govindasamy	620
105.	Agro-Intelligence: An End-to-End IOT and Edge-Al Integrated system for Precision Irrigation and Automated Crop Health Monitoring M**aheswari shanmugam**, **Vasudehaven V**, **Arun kumar V R**, **Arun hitesh R K**, Bh**arath kumar T D**	642
106.	Smart Power Quality Monitoring System Dr. L.Ashok kumar , Kumaravel.R , D.Gokul Karthik , K.Gowri Pandian	650
107.	Q-TRNG Robust Bid Encryption and Fraud Prevention Anne Jenefer ,M.E., Navanth Raja B, Pirajan S ,Vairasundharam S	656
108.	Entropy-Driven Nano-Sensor Fusion with QPSO Swarm Optimization for Predictive, Healthcare-Aware Disaster Response R.Rajalakshmi, Nelin Mercy N, Kalpana Magreat A, Mohana Selvi K, Jayalakshmi M, Janawarthini P	663
109.	Smart Wearable Safety System for Real - Time Proximity Monitoring and Emergency Response Sathiyapriya Shanmugam, Shahana Muralidharan, Shandhini Mohankumar, Syed Sulthana Beevi	669
110.	Design and Implementation of IOT-Based Smart Energy Meter for Ease Power Management Nithiya Dorairajan, Satheesh Kumar R, Srinivasan S, Vignesh K V	677
111.	Rural Care MediBot: An IOT-Driven Autonomous Healthcare Assistant for Remote Hospitals Nithya.D, Bharanidaran.M.S, Kavin Selvan.P.S, SaranKumar.S	681
112.	Comparative BER Performance Analysis of Conventional and TX-DWT Enhanced OTFS Systems for High-Order QAM over AWGN Channel Dr.S.Maheswari, M.R.Pavithra, G.Kerena, R.Deepa, S.Rupmithra, D.Nisha	687

113.	Arise: Autonomous Rover for Intelligent Sensing and Environment Monitoring Vasudevan Veeraraghavan, Hariprasath Shanmugasundaram, Gokulakrishnan Mani, Hariharan Rajesh Kannnan	692
114.	Smart IOT solution for real time worker health and safety monitoring in construction sites M Saraswathi, Aniruth A R, Anish Ragav V, Antony Ray S	697
115.	Design and Performance Analysis of Torus Slot Integrated Circular Patch Antenna for 2.4 GHz Applications S.Kirthika, Dr.S.Maheswari, D.Nisha, R.Deepa, S.Rupmithra, M.R.Pavithra	705
116.	Compact Octagonal Microstrip Patch Antenna with Circular Slots for 2.45 Ghz Applications Aruna Veeraselvam, G.Kerena, M.R.Pavithra, Deepa R	710
117.	Low-Power VLSI Design Techniques for Energy-Efficient Integrated Circuits Poonguzhali I, Varsha S, Shreyha Ja, Lakshitha J, Rithikaa R	716
118.	Smart Medicine Box for Cold Chain Monitoring Using IOT and Block Chain Rohan S, Senthamizh Selvan M, Sriram V, Dr.Elumalai G	721
119.	Adaptive Edge Intelligence Framework For Predictive Diagnostics In Smart Industrial Environments S.Sathiya Priya, Agathiyan B, Anthony Joenack P, Ahamed Naufal H	726
120.	Efficient Beamforming Approach for Direction-of Arrival Estimation Using Logarithmic Step-Size LMS Dr. S. Maheswari, R. Deepa, S. Rupmithra, D. Nisha, G. Kerenageorge, S. Kirthika	733
121.	Cognitive Energy Metering System Using Machine Learning Mrs.T.K.Preetha, Swathi Varshini.M, Sindhu.M, Sujipriya.G	737
122.	Proactive Discipline Monitoring System Krishna Kumar S, Kaamalesh K,Ajay Kumar S, Lathish Kumar D, Dr N Manojkumar	746
123.	AI-Based Condition Monitoring of Conveyor Belt Systems Using IOT, Machine Learning, and Deep Learning Ramapraba P S, Srivathsan S,Sudharshana Kannan P,Siddharthan S,Mithun J K,Sankar Vinith Kumar	751
124.	EcoSortNet: An Intelligent Multi-Stage Waste Segregation Framework Using Deep Learning and Robotic Manipulation Lavanya Dhanesh, Malini. A.G, S. Divyadarshini, S. Subhashini, Pavitra.D , Sivadharshini .V.R	756
125.	Development of Sensor for Detection of Microplastics Abinesh R, Akilan K, Durgesan E, Gopinathan M, Abishek B, Dr A Sivakumar	761
126.	A Novel Adaptive Protection Scheme Using Federated Learning for Microgrids with Variable Renewable Penetration Mrs.A.Kalaimani, B.Swetha, M.K.Harini, K.Durgasree, S.S.Shona, B.Yeshvetha	764
127.	Wind Energy Forecasting Using Machine Learning Models Dr. S. Deepa, Krithiga. BJ, Harini. G,Gopika. S, Sameena Devi. V	770
128.	Explainable Artificial Intelligence (XAI) for Probabilistic Solar Power Forecasting: A Post-Hoc Interpretation Framework	774

	Lekha shree S, KayalvizhiN.B, Rajarajeswari C, Madhumitha L, Monika I, Dr.S.Pushpa	
129.	Grid Integration of Renewable Energy Sources: Challenges and Solutions Mythili M, S.Vimala, Vasu Sheba Sharon, Elakkiya C.M, Lathika M, Addinki Manju Sri	781
130.	SecuraGuard: A Platform-Agnostic Offline Face Authentication Framework Leveraging Hardware- Anchored PKI Dr. N.Karthikeyan, Shanthosh K, Vasantha Kumar P, Vishal G, Velmurugan Pj, Yogaraji K	787
131.	Digital Twin-Based Predictive Maintenance Framework for Grid-Connected Power Transformers Using Hybrid Deep Learning Amudha Priya S, Dhivya Shree S, Sai Atchaya A, Swetha K, Subhashini S, Kunguma Kanishka K	793
132.	Digital Twin for Li-Ion Battery Health Management Using Physics-Informed Neural Networks Dr Shobana D, Gaberiala S, Keerthika A, Khaviya A, Akshayasri B, Asha A	800
133.	Deep Reinforcement Learning for Real-Time Voltage Control in Distribution Networks with High PV Penetration S.Balaji, Yukadharshini.S, Annointing Mary.M, Santhiya.T, Amirtha.U, Narmatha.A	807
134.	Solar Powered Smart Mobile Charger Amudhan S, Stephen Raj A, Vijayasarathy G, Srivathsan K R, D Silas Stephe	814
135.	Meta-Learning for Few-Shot Fault Diagnosis in Power Transformers Across Different Manufacturers B. Kandha Kumar, K. Rajaram, Saran A.V, Nanda Kumar.K, Yogesh.J, Mouli Raj.T	821
136.	Attention-Based Interpretability in Transformer Models for Solar Forecasting D.Iniyavan, T.Kishore, S.Harinathan, N.Kamesh, N.S.Anish, Mrs.M.J.Suganya	827
137.	Distributed Blockchain-Based Transactive Energy Framework for Peer-to-Peer Trading in Active Distribution Networks Mrs.S.Lakshmi, M.Naveenkumar, TRK.Sreevarshan, Jagadeesh.J, Ammaiappan.K, VasanthKumar.P	833
138.	Smart System Lighting with Traffic Analysis Using Iot-Based Adaptive Control Taresh V C, Yashwant M, Suriya V, Sanjay Kumar S, Sanjeishwer G S, Dr Dharmaprakash R	839
139.	Subterranean Cable Fault Distance Detection System Utilising a GSM Module P.Hariramakrishnan, Pranesh V, Ajay Karthikeyan R, Harish Jeyaraj M, Jesinth	845
140.	A Hybrid Deep Learning and Reinforcement Learning Framework for Smart Agriculture Using IOT Sensor Data B Prabha, Anni Princy B, E. Venitha, Rennaeshwaran S, NandhaKumar S	848
141.	WasteID: An AI-Powered Smart Bin with IoT Sensors and Blockchain-Based Incentive System for Sustainable Waste Management Bharani .M, Yukanraj Annamalai.J, Sri Amruthesh V, Vignesh M, Vijay Anand V, Syed Hameed S	854

142.	AI-Driven Distributed Unmanned Aerial Vehicle (UAV) Swarm System for Early Low-Altitude Missile Detection and Predictive Interception Support Prabha B, Akash M, Yugan Sai U, Monish Kumar B, Rahul Prasad R	861
143.	AI-Driven Detection of Fake Accounts in Social Media Platforms Dr.D.Sasi Kumar, Manikandan B, Y.Akhil, Gaali Yashwanth, Cimbili Lathish	867
144.	A Proposed Clinical Sign Language Communication Framework for ISL in Healthcare Dr. Anni Princy, Malathy S, Shamini A, Shivani R, Shyamala M,Sowmiya R, Thanya B	873
145.	Adaptive Multimodal Silent Speech Recognition System for Real-World Communication Dr Anni Princy, Keerthana Elumalai, Indhumathi M, Kaviya P, Dr Sasi Kumar, Esther Francis Elroy	880
146.	An Intelligent Multi-Sensor Fusion Framework for Real-time Threat Identification in Defence Surveillance Missions B Prabha, Anni Princy B, A Rizwan Basha, Aishwariya M, Rishika Muniraju	888

***Abstract*— A significant social engineering technique known as Phishing attacks remains and proves to be one of the persistent and also a evolving threats to the cybersecurity because using such attacks the attackers are successful in bypassing the traditional detection systems with ease and exploit the victims or target systems successfully also the traditional systems that use machine learning was able to provide high accuracy in laboratory tests but failed in handling the real time data and phishing mails Therefore DefenseGPT a two phase ensemble machine learning approach is introduced in this paper. The main duty of the first phase is to distinguish and identify whether the given mail is a phishing mail or a genuine ham mail, it is done by stacked ensemble classifier that includes models like XGBoost,CatBoost and Logistic Regression and for a meta learner Random Forest is used . For the second phase Random Forest classifier is used to classify and categorize the phishing emails to various intents and it achieved a 99% accuracy for categorization of all mails into Credential harvesting, Financial fraud, Malware delivery and Scam offer.Since this system takes important division between academic work and realtime deployment into account, it shows a good performance in wide range of real dataset created using seven collections.**

The main aim of developing this system was to not only detect the phishing mails but also exactly know what is the intent of the malicious actor to trap the target systems through phishing mail.

By knowing the exact intent of the attacker, this system enables to make efficient tackling and countermeasures to counter the said phishing attacks by knowing their exact intent and safeguard the sensitive information.

Keywords— phishing detection, ensemble learning, intent classification, machine learning, XGBoost, CatBoost, cybersecurity

I. INTRODUCTION

In today's world, phishing remains as a significant threat to users all around the world because attackers use various social engineering techniques like this to reveal user's sensitive data. Typical countermeasures such as SpamAssassin rule-based filters, and the typical security research is not keeping up with the campaigns that the newer actors are testing - not limited to email phishing but to obscured URLs, different phrasing, and means of obfuscating before returning to normal MIME content.

While their performance on labs climbs a significant 95%+ accuracy using public datasets, machine learning-inspired techniques experience a major drop of performance and do not maintain accuracy when faced by adversarial real-world email traffic niches. Several researchers have analyzed potential reasons for model loss, but within these limits are three areas of concern; standard static features that attackers consistently attempt, low transferability of accuracy with both synthetic and real email data, and little or no response against advanced attack techniques such as spear-phishing (SP) and business email compromise (BEC).

For the sake of conceptualizing an organizational use case, consider an institutional setting in which e-mail processing is a function of an e-mail security solution operating in financial services. The e-mail security solution needs to process thousands of e-mails on a daily basis (and a similar number of transactions) and must be accurate in most circumstances. While it is possible that a typical e-mail security solution would never miss social engineering attacks at scale, it will raise legitimate banking e-mails as phishing with the content of the words in the e-mail. Enter a multi-phase solution, such as Defense GPT, which allows organizations not only to identify phishing in a more accurate and efficient way, but also to describe the nature of the attacker.

To address these issues, we present DefenseGPT, an end-to-end two-phase machine learning pipeline that achieves the state-of-the-art in both detection performance and threat intelligence generation. Our framework represents the following main contributions:

1. Unique and Integer Stacked Ensemble Architecture: The best performing stack ensemble has XGBoost, CatBoost and logistic regression classifier with Random Forest as the meta-learner. This has been shown to have achieved 98.26% accuracy on real world data.

2. Intent-based Threat Classification: The first published work using phishing's intent-based analysis as a fine-grained classification of attacks into actionable threat categories has achieved 99% classification accuracy.

3. Real World Evaluation: The model was rigorously assessed through, a number of datasets consisting of seven public email collections so that it is ready to be implemented in real world usages.

4. Modularised Production Architecture: A GPU-optimized implementation of the model with operationalized model repositories and predictions architecture for production.

II. LITERATURE SURVEY

Chien and Khethavath [1] developed a feature-based classification model to defend users against phishing email threats using machine learning. The authors dealt with various feature sets; lexical features, header features, and body features to classify phishing emails and employed classifiers, the Random Forest and SVM, to maximize the authors' classification accuracy. The authors concluded that the combination of different feature sets greatly improved the effectiveness of phishing detection capabilities.

S. M. M. Ahammad et al. [2] propose an ML-PE-TA, a Machine learning - based phishing email text analysis model. They used TF-IDF vectorization and classifiers Naive Bayes, Decision Tree and SVM. They concluded that they were able to correctly classify phishing emails versus legitimate emails using TF-IDF and a machine learning model with above 95% accuracy.

G. Kanaan et al. [3] experimented with machine learning methods and deep learning methods to test deep learning for Arabic email spam detection. They used CNNs, LSTMs, and traditional classifiers like Logistic Regression and Naive Bayes classifiers. The authors show that deep learning models did outperform classical models and with regard to linguistic nuance, the capability of deep learning models to detect multilingual phishing seems reasonable for a phishing detection platform.

K. Kalaiselvi et al. [4] proposed an ensemble learning method for identifying email fraud attacks. We achieved high recall and precision and combined classifiers again termed ensemble learning classifiers, using the classifiers of XGBoost, AdaBoost and Random Forest. Kalaiselvi et al. [4] find using an ensemble method produced better performance figures than using single classifiers and established that ensemble methods provide robust performance against different phishing methods.

I.T. Almalkawi et al. [5] enhance email security using machine learning-based detection of phishing attempts. They utilized a real dataset to train supervised classifiers and in addition to their classifiers, they also did many different things like dataset construction, feature engineering, etc. to enhance the found rate of phishing attempts. Their study focused on the improvements in true positive rates, the rate of phishing emails discovered, by examining their false positive rates against standard rule-based filters.

R. Abadla et al. [6] present IPED-MFA, an analysis system based on multi-features that can provide intelligent phishing detection. They fuse URL-based, header-based, and content-based features that were selected from many machine-learning models. Their hybrid approach could increase the detection rates for zero-day phishing attacks.

S.A. Maeli and A.U. Surwade [7] propose an ensemble of Random Forest, Gradient Boosting and SVM for predicting phishing emails based on feature selection and analysis. They find that through feature selection their model's generalization improved remarkably, demonstrating that it is possible to integrate both ensemble learning and feature selection.

A. Kovač et al. [8] provide an overview of a few machine learning algorithms used to address phishing attacks in electronic mailing services. This research outlines procedures utilizing Decision Trees, Random Forest, and Neural Networks with its findings showing hybrid and ensemble models, as most efficacious for real time usage.

P. Maturure et al. [9] developed a hybrid machine learning model that merges supervised classifiers with unsupervised clustering for phishing detection. The implementation of supervised learning with clustering reduces the false positive rate by improving the boundary of the classifiers with k-means clustering in a post-processing step.

L. S. S. A and co. [10] create an e-mail spam detection model using logistic regression. They train their model using balanced datasets and get near equal accuracy and low computation type perimeter when applying their logistic regression model done by way of feature scaling.

U. Singh et al. [11] studied spam email assessment with a machine learning and data mining framework. Naive Bayes, Decision Trees, and SVM were employed to assess the datasets. Their study suggested that ensemble approaches are more resilient to inconsistencies in patterns in the dataset.

Y. P. Atmojo et al. [12] have been focusing on spear-phishing attack detection, via monitoring network traffic, using base classifiers such as Random Forest and XGBoost in the machine learning (ML) flow. Their approach is unique because they use more than just email contents to detect for spear-phishing attacks; they have been able to find some indicators at the network level such as session data and packet flow which have allowed them to detect spear-phishing attacks that are much more targeted--including ones where advanced obfuscation is used.

R. Rajoju et al. [13] propose a Random Forest based text phishing detection system which incorporates n-gram features and TF-IDF representations to better represent the subtle nuances in linguistic features present in phishing emails. Their results yield very high accuracy and F1 scores, and the development of their proposed model results in both models that perform well across large schemes of data while maintaining a low false positive scheme.

K. K.V. et al. [14] presented a novel method for phishing detection in thread sharing networks. The authors' method uses the SVM and XGBoost classifiers to explore the active thread communication and alert users when it detects a potentially suspicious activity early, therefore limiting the chances of spreading phishing links to other users.

R. Dhanalakshmi et al. [15] provide a solution for phishing domain detection with an AI approach based on both lexical features of URL, WHOIS features, and domain reputation. Their model has high performance for malicious domain detection before users interact with it, thus serving as a form of defense against web-based phishing attacks.

S. S. V et al. [16] provide a comparative study of different machine learning models to detect phishing including Random Forest, Logistic Regression, and XGBoost. The authors conclude that tree-based ensemble models are best based on precision and recall and so are naturally aligned with security uses cases.

S. Bagui et al. [17] examine how machine learning and deep learning were used to classify phishing emails. They observe that deep learning models tend to be more generalized and less biased than classical algorithms when trained on enough training data, found that the LSTM networks performed the best overall.

A. I. Champa et al. [18] provide a comprehensive study of curated phishing datasets, and review a number of feature engineering processes. The authors conclude that in respect to hybrid feature selection accuracy, the accuracy was greater than any one of the features lexical, header, or content alone.

Rabbi et al. [19] developed Phishy?, a phishing identification framework that uses word embeddings and an ensemble classifier to make better use of the contextual meanings of words. An ensemble classifier is a way to obtain a higher recall rate; recall is important because it mitigates the chances that phishing e-mails will be missed in a high risk environment.

S. M. R. Hegde et al. [20] were investigated social engineering based phishing detection, factoring in behavioral features (e.g. click rate, response time) with content-analysis features in email. So this two phase detection system would successfully improve the detection rates of these kinds of attacks.

III. PROPOSED METHODOLOGY

The solution this system suggests is to use an advanced two phase machine learning pipeline to implement the workflow that will accurately detect the threats and prevent any questionable actions and intentions that are made by the malicious actor.Thus the following architecture consist of six modular structure for phishing detection.

A. Dataset Construction & Preprocessing

The dataset that is used for the system implementation are taken from publicly available Kaggle source: PHISHING_EMAIL, SpamAssassin, CEAS_08, ENRON, LING, NAZARIO and NIGERIAN_FRAUD.

The system uses aggregation rather than going with merging all the data because it should have multiple representation of genuine communications and also to have various phishing attacks.Also in preprocessing there is a huge amount of normalization in text.

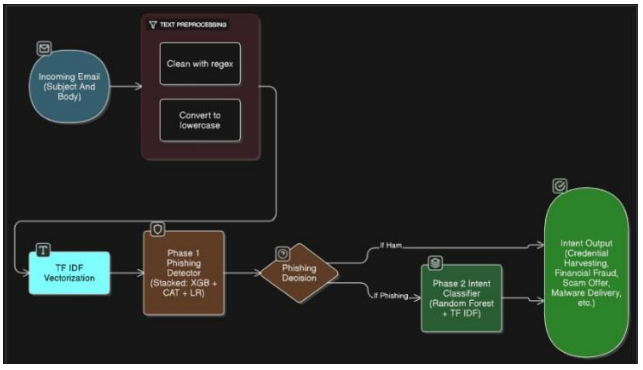

Figure 1: System Architecture

```
def clean(text):
    text = re.sub(r"http\S+|www\S+|https\S+", '', text, flags=re.MULTILINE)
    text = re.sub(r"[^a-zA-Z ]", "", text)
    text = re.sub(r"\s+", " ", text)
    return text.lower().strip()
```

B. Feature Extraction Framework

For extracting the features, the system used Term Frequency-Inverse Document Frequency (TF-IDF) for doing vectorization in order to convert the pre processed texts into numerical representation. For main model it is 5000 dimensions while the other model uses 3000 dimensions vector to increase the speed.

TF-IDF Formula:

$$TF\text{-}IDF(e,g) = TF(e,g) \times \log(T/DF(t))$$

where TF(e,g) is term frequency, T is total documents, and DF(t) is document frequency.

C. Phase 1: Stacked Ensemble Detection The primary detection module applies a sophisticated stacking ensemble architecture: Base Learners: XGBoost: GPU-based gradient boosting specialized for tabular data CatBoost: gradient boosting robust to overfitting Logistic regression: linear baseline that can output explanations Meta- Learner: A Random Forest classifier with 150 estimators using the predictions of the base learners.

Stacking Architecture:

python

```
stacked_model = StackingClassifier(
    estimators=[
        ('xgb', xgb),
        ('cat', cat),
        ('lr', lr)
    ],
    final_estimator=rf,
    passthrough=False
   )
```

D. Phase 2. Intent Classification System.

Under Development - All phishing emails discovered in Phase 1, were subjected to stricter intent classification that will use a

specific Random Forest based classifier that will only consider emails classified as a phishing, taking into account users email address and, we will research a hierarchy of intent classifications domains. . We will classify the taxonomy into a total of four dimensions:
Credential Harvest: attempts specifically intended to steal users authentication credentials
Financial Fraud: as it states, loss of money, financial fraud
Malware Delivery: delivery of malware
Scam Offer: false promotional offers

Feature Fusion Formula:
text
F_fused = Σ(W_i × F_i) for i=1 to n
where W_i represents weights assigned to each modality's feature vector.

E. Model Training And Optimization

The training pipeline utilizes fast GPU (Graphical Processing Unit) in the case of using the XGBoost, or CatBoost, which minimizes time taken to train the model. The pipeline does utilize joblib, serialization for robustness, logging, and persistence of model.
GPU Config:
test
```
xgb = XGBClassifier(
    tree_method='gpu_hist',
    predictor='gpu_predictor',
    gpu_id=0,
    use_label_encoder=False,
    eval_metric='logloss'
)
```
F. Deployment Architecture

The system is modular in design allowing for local testing and processing for any possible production deployment at a point in time. You currently have two options for the user to interact with the system using either the command line interface (CLI), or importable python functions.
Once again the CLI use case here is for local validation and demo, the only input the user will provide is the email subject and body the the system will retrieve and classify the e-mail. This is probably the better option to use when debugging or do a quick test on the model but also to demo the operational capability of the model for your stakeholders without having all of the requirements implemented.
So, while this system is not a full fledged REST API / web service, it is possible to engage with the module implementations of the model and vectorizer to develop and bootstrap into a larger context. Referring back to the earlier example, you will be able to load the instantiated model(s) and call them programmatically, so there is a potential for building more generic email processing service at scale. Generally, the design works to support a production deployment scenario: starting with 'working on a handwritten response time data set' (to fully automated processing system, which may actually work as a model for an email filtering service.

IV. EXPERIMENTAL APPROACH.

In this section it presents an overview of the hardware and software environment, variables of the dataset, characterization of the evaluation methods to determine the performance of the DefenseGPT system. The experimental design was set up to allow for reproduction and to fully explore the feasibility of the models within the practical environment.

A. Hardware/Software Environment

All experiments were conducted on a high-performance workstation with an NVIDIA RTX 4050 Laptop GPU that has Ada Lovelace architecture and CUDA compute capabilities of 8.6. The reasons for hardware selections were to use the GPU accelerated computing features of the XGBoost and CatBoost libraries that further reduces model training time for larger datasets. The workstation has 16GB of DDR5 RAM, which means in-memory data manipulations and TF-IDF vectorizing was never slowed down due to memory. An NVMe Solid State Drive (SSD) was used for speed and efficient, natural, I/O operations while transferring files quickly, as it must be an issue for memory with datasets larger than 160,000 records, and in order to load it into the database correctly.

The whole software stack was built entirely using Python 3.9, as well as various open source libraries for machine learning and data science, including:

Pandas: For loading, cleaning and manipulating data.

Scikit-learn: For implementing the TF-IDF vectorizer, Logistic Regression, Random Forest, and Stacking Classifier.

XGBoost & CatBoost: for implementing the GPU accelerated boosting models.

Matplotlib & Seaborn: for creating visualizations of the confusion matrix.

Joblib: for serializing and persisting models to allow saving and loading of trained models for prediction.

B. Dataset Features

In order to ensure reliability and also ensure generalization of the model, we curated a > > comprehensive dataset from seven available email collections: PHISHING_EMAIL, SpamAssassin, CEAS_08, ENRON, LING, NAZARIO, and NIGERIAN_FRAUD. By curating a dataset from several email collections, we are reducing overfitting to one source of data, while exposing the model to a diversity of writing styles, phishing attacks and types of legitimate email. After we merged the email collections together and removed duplicates, our final dataset consisted of over 164,000 unique email messages. The dataset was also very balanced between Phishing and Ham, labeling approximately in the range of half "Phishing" (target emails) and half "Ham" (legitimate emails), demonstrating that the class imbalance in the data would not induce skewed performance from the model.

TABLE I. Dataset Description

Dataset	Emails	Category
SpamAssassin	6,047	Spam / Ham

Dataset	Emails	Category
Enron	30,000+ (subset has been used)	Legitimate
CEAS-08	35,000	Spam / Ham
Ling-Spam	2,893	Spam / Ham
Nazario Corpus	1,565	Phishing
Nigerian Fraud	1,000+	Scam / Phishing
PHISHING_EMAIL	18,000+	Phishing / Ham

The second stage of the pipeline employed a custom intent classification dataset. The dataset that is used for implementing this system contains about 14,270 emails that were labeled in advance as phishing mails and classified as one of the four following intents they are: Credential harvesting

Financial fraud

Malware delivery

Scam offer

Each category were given the sample distribution that represents in real world as credential harvesting as the most common attack type.

C. Evaluation Procedures

In this system the models that are trained are evaluated on a standardized set of metrics to show the evaluation of performance that includes accuracy, recall, precision and f1-score.

In general accuracy represents the overall correctness, to provide the understanding of performance on both negative and positive classes recall and precision are used here.

This careful evaluation is done so because when it comes to security applications, there will be a high possibility to give false positives and false negatives which can significantly affect over all security and lead to huge risks.

The detection and intent classification models were treated the same in respect to data splitting prior to data preparation for both models, the datasets were split to 80% training and 20% test. Instead of random splitting the data, the train_test_split method from scikit-learn was used with random_state=42 to ensure reproducible results. Furthermore, stratified-sampling was used when splitting to maintain the same proportions of class labels within the training and test sets that were in the original datasets, which primarily applied again to intent classification due to certain categories containing considerably fewer recorded instances than the other categories. Through stratifying we can train and test reliably on a sample that contains some amount of all the categories

V. RESULTS AND DISCUSSION

A. Phase 1: Phishing Detection Performance

Our stacked ensemble has performed extremely well for the binary classification task, achieving an overall accuracy of 98.26%, while having roughly balanced true positive and true negative values for both classes.

The confusion matrix indicates that we correctly classified 15,519 legitimate emails and 16,784 phishing emails as phishing emails, although with some misclassification (271 false positives and 301 false negatives) that occurred.

TABLE II. Phishing Detection Table

Class	Precision	Recall	F1-Score	Support
Ham (0)	0.9828	0.9810	0.9819	15,820
Phishing (1)	0.9824	0.9841	0.9832	17,055
Accuracy			**0.9826**	**32,875**
Macro Avg	**0.9826**	**0.9825**	**0.9826**	**32,875**
Weighted Avg	**0.9826**	**0.9826**	**0.9826**	**32,875**

Figure 5:Intent Classification Output

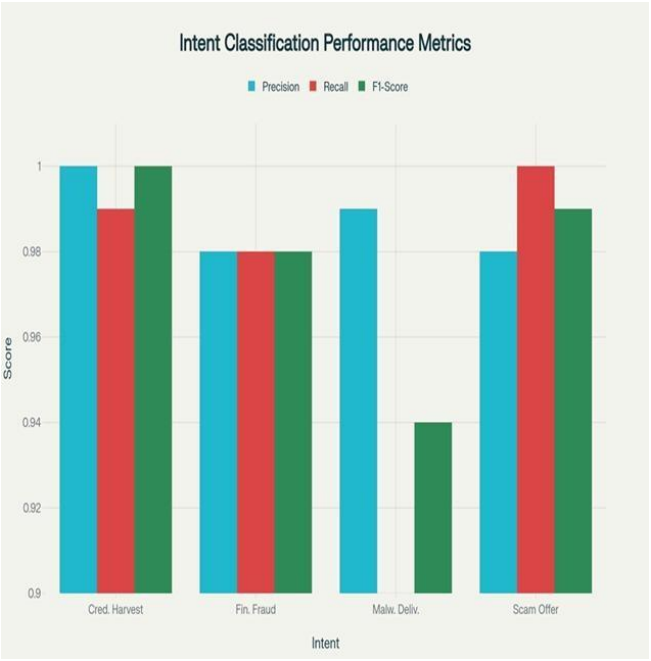

Figure 6: Intent Classification Performance Metrics

C. Comparisons

A comparative analysis was performed against established phishing detection models reported work based on the current literature. Various machine learning classifiers, including Support Vector Machines, Random Forest, Logistic Regression, and Stacking models, achieved accuracy rates between 94% and 97%. The proposed

DefenseGPT system, on the other hand, achieves a detection accuracy of 98.26% using a stacked ensemble architecture that combines XGBoost, CatBoost, and Logistic Regression with Random Forest as the meta-learner. This comparison analysis shows that the proposed system not only shows more accuracy but also introduces an additional capability to identify the intent.

D. Performance of the System Architecture

This system's architecture provides performance metrics that prove its consistency with following estimations:

Processing Pipeline:

1. Text preprocessing: ~0.1ms per email
2. Feature extraction: ~2.3 ms per email
3. Phase 1 Detection: ~1.8ms per email
4. Phase 2 Intent Classification: ~ 1.2ms per email (if the system detects of any phishing attacks)
5. Overall processing: ~ 5.4 ms per email (average)

Memory Performance:

Model Size: 49 MB (Phase 1) + 33.6MB (Phase 2)

VI.CONCLUSION

This paper features a new system DefenseGPT,with a new two-phase machine learning ensemble approach that has both high accuracy with 98.26% of phishing detection and 99% with classifying the intent. While this system has its own flaws,it primarily focuses on training the model on real world datasets so that the model is robust and can have the ability to classify the real time mails.

***Abstract*— The ML-Based Crop Recommendation system is a smart tool that helps farmers pick the best crops for their fields. It makes smart choices based on information about the soil, the weather, and the environment. The system uses machine learning, specifically the Random Forest method, to look at things like the levels of nitrogen, phosphorus, and potassium in the soil, as well as the pH, temperature, humidity, and rainfall. By looking at these things, it gives farmers good advice that can help them grow more and keep their crops from getting sick.It has a chatbot and voice assistant that speak local languages to make it easier to use. This makes it more inclusive for farmers who may not be able to read or speak the main language. The system also learns from what users say and new data over time, so it keeps getting better and stays up to date.This system changes the way people get traditional farming advice by giving them personalized tips and help right away. It could also get bigger in the future by adding features like predicting pests, predicting market prices, and sending weather alerts. In general, it's a big step forward in making farming smarter, easier to get to, and better for the environment.**

I. INTRODUCTION

Agriculture is very important for India's social and economic growth. It adds a lot to the country's overall economic output and helps a lot of people make a living. But the agriculture sector is facing a lot of big problems right now. These problems include weather that is hard to predict, soil that is getting worse, bad crop choices, and wasteful use of resources. A lot of farmers still use old methods or local knowledge, which might not work well because the environment and market are always changing.These old ways of farming often result in low crop yields, money problems, and farming methods that aren't good for the environment.With new technologies like Machine Learning (ML), Artificial Intelligence (AI), and Data Analytics, agriculture can now be changed.These technologies can look at a lot of data about farming and the environment and give farmers useful advice.The ML-Based Crop Recommendation System is one of these tools that helps farmers choose which crops to grow by using these technologies.

The Random Forest algorithm is a strong and accurate machine learning method that this system uses. It can handle complex data sets. The model learns from a lot of different things, like soil nutrients (nitrogen, phosphorus, and potassium), temperature, humidity, pH levels, and rainfall. The system uses this information to suggest the best crops for different types of soil and climates. This helps increase yields and lowers the risk of picking the wrong crops.

By merging data science, machine learning, and a user-centric design, this ML-Based Crop Recommendation

System links technology with traditional farming. It gives farmers accurate information, encourages environmentally friendly practices, cuts down on the need for manual advice, and helps the country's food security and rural development. This project represents a step toward creating a smarter, more accessible, and technology-driven agricultural system in India.

II. LITERATURE SURVEY

[1] Kumar et al. presented a system of machine learning to recommend the cultivation of crops based on environmental conditions such as soil nutrients, temperature, humidity, and precipitation. In this study, various methods were evaluated, including decision trees and random forests. The results indicated that the random forest method was able to provide better accuracy and reliable prediction of which crops would produce and be produced.

Singhal et al.[2] have published an in-depth analysis of different types of agricultural crop selection technologies, including Machine Learning, Artificial Intelligence (AI), Internet-of-Things (IoT), and Deep Learning for use in producing optimal crop yields. They address various models developed by researchers in these areas and provide summaries of how integrating multiple technologies can enhance the quality and speed of making agricultural production decisions.

[3] The research carried out by Patel et al. involved using machine-learning algorithms such as decision tree, support vector machine (SVM), and naive bayes to create a model that predicts agricultural yield based on both soil nutrient and climate data. Their results indicate that machine learning has potential utility in helping farmers determine what crops they will grow.

[4] Sharma et al. put forth a cultivation recommendation framework, which utilized supervised machine learning methods. Inputs to the system were based on environmental conditions (weather and soil characteristics), which were used to produce a prediction. Performance evaluation of their model showed greater accuracy when producing results based on large agricultural data sets.

[5] By employing Random Forest and Artificial Neural Networks, Singh et al., created a data-driven crop selection model. The researchers found that ensemble models produced superior predictive accuracy over models that were built from only one algorithm alone.

[6] Using Decision Trees and K-Nearest Neighbors, Ramesh and Patel produced a novel recommendation system to determine the crop that will be best suited for specific soil types and environmental characteristics. All prediction methods used in this research produced good results with agricultural data sets using a Decision Tree model as the best-performing method.

[7] Gupta et al. developed a machine-learning system to predict an agrarian output, as well as provide advisements related to crop selection based on climatological/soil data. The system was trained using historical agrarian data and provides accurate predictions that enable increased agrarian productivity for farmers.

[8] An Internet of Things-based crop forecasting platform was developed by Sharafat et al. using machine learning algorithms with real-time soil sensor readings. Their prediction system uses Random Forest and Gradient Boosting algorithms for machine learning and, by allowing the systems to operate on edge devices, they can be implemented quickly in farming environments.

[9] Rao and others examined how Support Vector Machine (SVM) and Random Forest (RF) algorithms could be applied to crop recommendations. It was concluded that RF provides better overall accuracy than SVM because it can handle larger data sets with more complex feature-to-feature relationships.

[10] The Crop Advisory System developed by Kumar et al. helps determine what type of crop would be best suited to an area based on environmental factors using various methods of Machine Learning. The authors stress that preparing the data properly through pre-processing and selecting appropriate features will enhance the systems' performance.

[11] A machine learning model developed by Ahmed et al. recommends crops according to both weather and soil fertility. The system was able to classify crops with a high level of accuracy and illustrates the possible uses of intelligent systems in agriculture.

[12] Through experiments with Naïve Bayes and Decision Tree for crop forecasting, Das and others found that Decision Trees provided more accurate forecasting than Naïve Bayes when applied to agricultural data.

[13] Mehta and colleagues developed an online crop approach by utilizing machine learning methods on the internet from farmers entering their individual soil or other environmental characteristics into an online platform to receive crop recommendations.

[14] Patel and Shah proposed a predictive model for crop selection using ensemble learning algorithms. Their research highlighted that combining multiple machine learning models can improve prediction accuracy and reliability.

[15] The authors, Singh and Kumar, the authors, made a smart agriculture system that uses machine learning and environmental monitoring systems. The machine learning models use data about the soil and weather to help suggest what kinds of crops to grow in a certain area. This will help farming that is good for the environment.

III. PROPOSED METHODOLOGY

The suggested Machine Learning-Based Crop Recommendation System is designed to give farmers intelligent, data-driven, and user-friendly agricultural assistance. In order to provide farmers with precise crop advice in their preferred language, it employs machine learning techniques in conjunction with multilingual and voice-based tools. As described below, the entire procedure is divided into a number of major steps.

1. Data Collection and Preparation

The system begins by collecting agricultural data from reliable sources, such as open government databases, the Indian Council of Agricultural Research (ICAR), and Kaggle. Important environmental and soil data, including soil pH, temperature, humidity, rainfall, nitrogen (N), phosphorus (P), and potassium (K) levels, are included in the dataset. The data is cleaned and ready to correct any incorrect or missing entries after it has been collected. In order to properly manage the data, verify the values, and arrange everything so that the model can be trained efficiently, Python tools like Pandas and NumPy are utilized. This procedure is crucial to ensuring that the data is trustworthy and accurate, which improves the model's ability to make predictions.

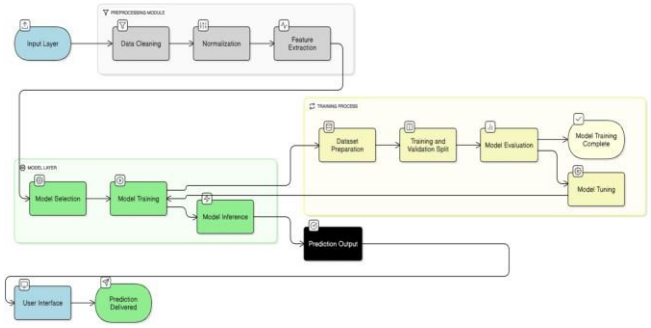

Figure 1: System Architecture

2. Model Development using Random Forest Algorithm

The Random Forest algorithm, which was chosen because it is precise, capable of handling big data sets, and adept at handling intricate and non-linear relationships, is at the core of the system.Using the prepared data, the model is constructed to identify relationships between soil properties and the most productive crops.

The following are included in the training process:
Separating the data into two portions: one for model training and another for performance evaluation.
Nitrogen (N), phosphorus (P), potassium (K), pH level, temperature, humidity, and rainfall are examples of input features that are used in the model.
Allowing the model to forecast which crops would work best in those circumstances.
Measures like accuracy, precision, and recall are used to assess the model's performance after it has been trained.
The experiments' findings demonstrate the system's effectiveness, with a success rate ranging from 94% to 96%. This demonstrates the system's dependability and effectiveness in recommending the appropriate crops based on soil and climate conditions.

3. Multilingual Chatbot Integration

A multilingual chatbot interface is included to make the system more user-friendly and inclusive.Farmers from various regions can easily access and comprehend the system's information thanks to this feature, which enables interaction in multiple languages, including Tamil, English, Malayalam, Hindi, and Telugu.
Natural Language Processing (NLP) is used by the chatbot to comprehend user inquiries and offer pertinent responses.

The crop recommendation is returned in the same regional language after the user's input has been translated into a language that the machine learning model can understand. This eliminates the language barriers that frequently prevent farmers from utilizing agricultural technology and facilitates clear communication in both directions.
.

4. Voice Assistant Integration (Speech-to-Text and Text-to-Speech)

The system has a voice assistant module in addition to text-based interaction, which makes the platform more user-friendly for those who might not be highly literate.
In order for the system to comprehend a user's query, the Speech-to-Text feature converts spoken words into text.
In contrast, the Text-to-Speech feature allows users to hear the system's responses by translating them into spoken words.

This enables farmers to interact with the system in a natural way and receive responses in their native tongue.
To guarantee accurate and clear voice processing and responses, services like Google Speech Recognition, gTTS, or Azure Speech Services can be utilized.

5. Feedback and Model Improvement

Farmers can provide feedback based on their actual experiences in order to maintain the system's accuracy and relevance over time. The model is updated and improved on a regular basis thanks to this feedback regarding which crops grow well and how much they produce. This continuous process allows the system to adapt to changes in farming practices, weather patterns, and soil quality, ensuring that the advice remains relevant and up to date.

6. Output and Result Interpretation

The system employs a trained machine learning model to process the data that the user provides about the soil and environment, either by typing it in or using the chatbot.
The outcomes consist of:
the ideal crop to grow in those circumstances.
a success rate or confidence score that indicates the degree of certainty of the forecast.
The recommendation is provided in both text and voice output with a brief explanation.

.

IV. EXPERIMENTAL APPROACH.

This section outlines the experimental setup for the crop recommendation chatbot, designed to assist farmers in selecting optimal crops based on soil and environmental conditions. It covers the hardware and software environment,

dataset features, and evaluation procedures, ensuring a reproducible and practical setup for agricultural applications

A. Hardware/Software Environment

The chatbot was made and tested on a simple laptop with an Intel Core i5 processor (2.4 GHz) and 8GB of RAM, which was enough to handle the 1,000-row dataset. A 256GB SSD made it easy to quickly load and store data. You don't need a GPU because standard hardware works well with lightweight machine learning models like Random Forest that are used to predict crops. This cheap setup makes the chatbot useful for people who live in rural farming areas.The following libraries were used to build the software in Python 3.9:

- **Pandas:** For dataset loading and cleaning.
- **NumPy**: For numerical calculations and data scaling.
- **Scikit-learn:** For data preprocessing (e.g., normalisation), Random Forest model training, and performance evaluation (accuracy, precision, recall, F1-score).
- **Flask**: For developing the chatbot's web interface so that it can be accessed on computers or phones.
- **Matplotlib:** For displaying model outcomes, such as confusion matrices.
- **Joblib**: For quickly making predictions by storing and loading trained models.

B. Dataset Features

To make sure that the results are reliable and can be applied to other situations, The dataset has 1,000 records that are meant to show how farming works in India based on information from groups like the Indian Council of Agricultural Research (ICAR). It has:

- **N (nitrogen):** 10–150 kg/ha of soil nitrogen.
- **P (Phosphorus):** Phosphorus in the soil (20–80 kg/ha).
- **K (Potassium):** 10–300 kg/ha of soil potassium.
- **Temperature**: 10–40°C.
- **Humidity**: 30–90%.
- **pH:** 5.0–8.0 for soil.
- **Rainfall**: 300–2500 mm.

Thirteen crops—millet, sugarcane, wheat, cotton, rice, soybean, pulses, lentils, blackgram, pomegranate, coconut, maize, and coffee—are targeted. In order to prevent bias, each crop appears roughly 77 times, guaranteeing a balanced dataset. The data was created with verified ranges, no duplicates, and realistic conditions in mind.

C. Evaluation Procedures

A standardized set of performance metrics, including accuracy, precision, recall, and F1-score, were used to evaluate the crop recommendation models. These metrics were chosen to offer a thorough assessment of the chatbot's efficacy:

- **Accuracy:** Indicates overall performance by calculating the percentage of accurate crop recommendations.
- **Precision**: Essential for guaranteeing farmers receive trustworthy recommendations, it shows the percentage of suggested crops that are accurate.
- **Recall**: Reduces missed recommendations by calculating the percentage of real crop instances that were accurately predicted.
- **F1-score**: Provides a single performance metric by balancing recall and precision, particularly for less common crops like coffee or pomegranate.

In agricultural applications, where inaccurate recommendations could result in poor crop choices that impact yields and farmer livelihoods, these metrics are crucial. To guarantee practical utility, false positives (recommending an unsuitable crop) and false negatives (failing to recommend a suitable crop) were closely monitored.

Using Scikit-learn's train_test_split with random_state=42 for reproducibility, the dataset was divided into 80% training (800 records) and 20% testing (200 records).The main model was a Random Forest Classifier, which was selected due to its efficacy in multiclass classification and resilience to noisy data. For comparison, other models (such as K-Nearest Neighbors and Decision Trees) were tested.

V. RESULTS AND DISCUSSION

After the model was trained using the agricultural dataset, the machine learning agricultural model's performance was evaluated using various input values. In order to determine which crops would be most appropriate for a given plot of land, the model assessed the soil nutrition value and environmental factors (such as temperature, humidity, rainfall, nitrogen, phosphorus, potassium, and soil pH).

The crop recommendation system correctly predicted the appropriate crop for the majority of the input conditions, according to the test results. For example, "Rice" was successfully recommended when a user entered soil and environmental conditions that matched rice cultivation. The model found a strong correlation between the input conditions and the right crop for that dataset, as evidenced by the recommendation's confidence level of roughly 92%.CropBot, the model's user interface, is made to facilitate easy user interaction. The user enters data in designated input fields, the system uses the trained model to assess the user's data, and the user is then shown the crop and a probability (or confidence) score associated with that choice.Because it enables users to utilize the interface in their native tongue, the system's multilingual capability is a crucial feature. This feature makes it easier for users to interact with the system, no matter where they are in the world.

The experiment demonstrates how agricultural data can be analyzed using machine learning techniques to provide precise crop yield forecasts. It also shows how farmers can more effectively manage crop production by using data-driven strategies.

While the model was effective, the accuracy of predicted outcomes is dependent upon the quality and size of the training datasets; therefore, the effectiveness of the system would be

further enhanced by using both greater quantities of data and real-time weather data.

Overall, the experiment has demonstrated that the crop recommendation model has the potential, to provide crop recommendations and be a supportive tool in modern farming operations.

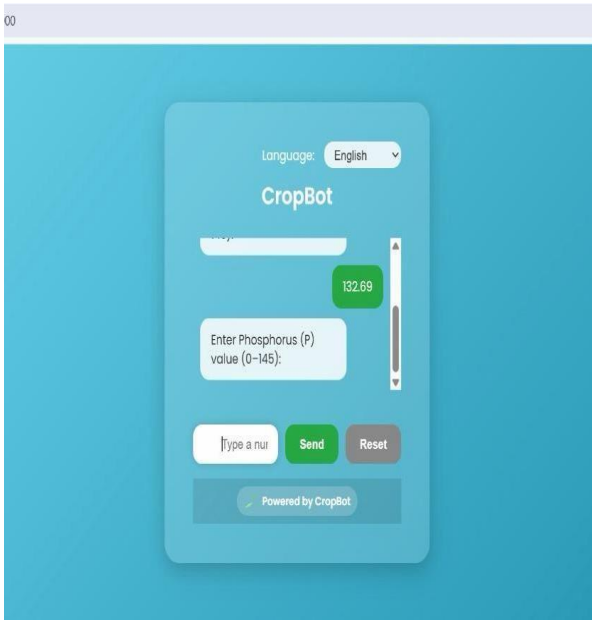

Figure 2: Detection Output

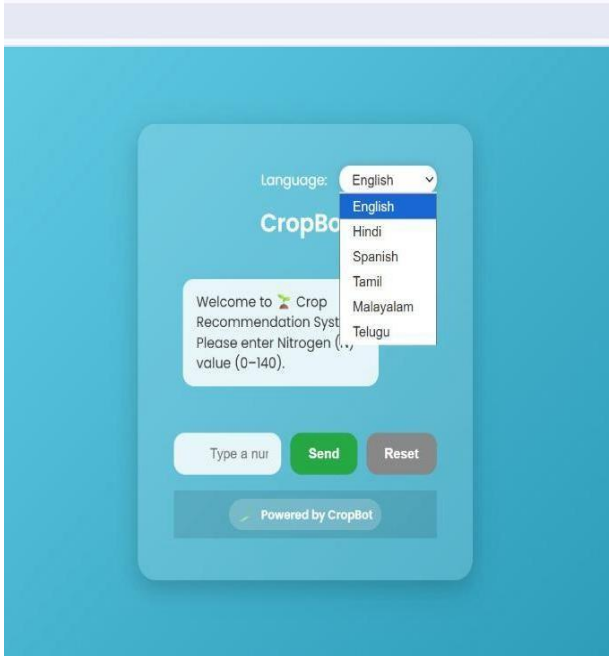

Figure 3:Detection output

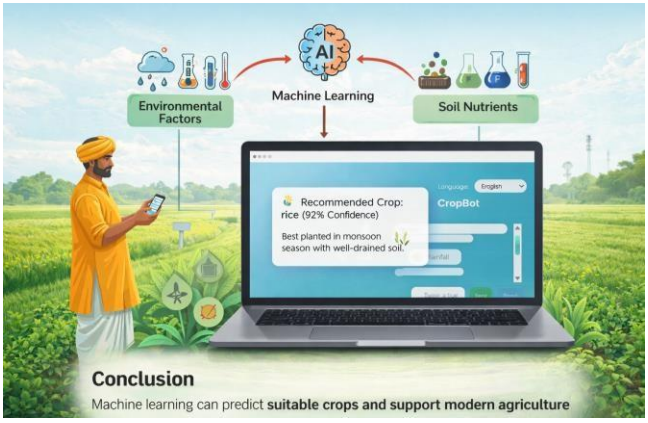

Figure 4: results

VI. CONCLUSION

Using machine learning we have created a Data-Driven Crop Recommendation System as a means of helping farmers determine which crops may best suit their farmland based upon soil nutrient levels, as well as other external environmental factors.The ML algorithm analyzes parameters important to crop growth including nitrogen, phosphorus, potassium, temperature, humidity, rainfall, and pH level of the soil. With all of this information collected, an appropriate recommended crop will then be developed based upon these modeled parameters.

The system evaluates both historical records of actual field data (agricultural data) as well as incorporates current weather patterns into the prediction algorithm, ultimately providing accurate crop recommendations.The CropBot provides users with an easy-to-use interface for entering required fields and waiting for an output in a concise and clear manner as the product of the algorithm performed by the model.

This research indicates that ML techniques can further increase farming yields and provide a greater likelihood of actual crop production by providing accurate data-based recommendations for planting crops; thereby decreasing the probability of planting a crop which will not yield due to environmental conditions.In future research, this project can be improved by: integrating real-time weather data, creating an algorithm that will provide fertilizer recommendations, and developing a mobile application to provide greater access to farmers.

ABSTRACT : Road safety has emerged as a serious concern because of the rising number of accidents triggered by drunk driving and late emergency response. Most of the current vehicle safety solutions are designed to address either alcohol detection or accident detection, but not both. To overcome this problem, this project aims to develop an IoT Enabled Driver Safety System for Accident Detection and Alcohol-Aware Engine Control, which combines both preventive and responsive safety measures in a single embedded solution.

The proposed system uses an alcohol sensor to monitor the driver's breath as soon as the driver enters the vehicle. If the alcohol level detected is above a certain threshold, the system immediately triggers a warning message and prevents engine ignition, thus preventing drunk driving. For accident detection, a MEMS accelerometer is used to continuously monitor the vehicle's motion and detect any sudden abnormal acceleration, thus detecting a collision. Once an accident is detected, the system automatically triggers an emergency alert message to pre-stored contacts through GSM communication.An Arduino Uno is used as the central controller, ensuring the system's proper functioning. The proposed system is cost-effective, efficient, and ideal for real-time vehicle safety solutions.

Keywords - IoT, Driver Safety, Alcohol Detection, Accident Detection, GSM Alert, Arduino Uno, MEMS Sensor.

I. INTRODUCTION

Road accidents are becoming a major concern due to the increasing number of vehicles on the road and reckless behavior like driving under the influence of alcohol. The effects of accidents can be further aggravated if there is a delay in seeking help in times of need. This is where the need for intelligent safety systems arises that can prevent accidents as well as provide immediate assistance.

Advances in embedded systems and IoT technology have made it possible to monitor the driver's status and the movement of the vehicle in real time. Sensors are continuously collecting data, microcontrollers are making

decisions instantly, and GSM communication enables automatic sending of alerts.

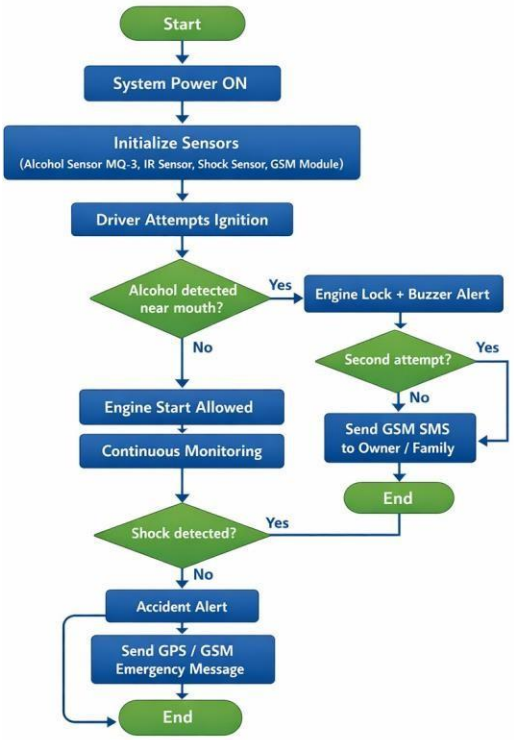

FIG 1 : FLOW CHART

The proposed project will focus on the development of an IoT-capable driver safety solution that will detect the presence of alcohol and limit the use of the vehicle if required. The project will also employ a MEMS accelerometer to detect accidents and send automatic alerts to the pre-defined contacts.

II. OBJECTIVE

Project Objectives for IoT Enabled Driver Safety System for Accident Detection and Alcohol-Aware Engine Control :

- Design and develop a driver safety system to reduce road accidents due to drunk driving.
- Detect the presence of alcohol in the driver using an alcohol sensor and restrict the use of the vehicle when driven under the influence of alcohol.
- Prevent drunk driving by taking immediate warning and control measures as soon as alcohol is detected.
- Accurately identify vehicle accidents using a MEMS accelerometer by sensing sudden abnormal acceleration patterns.
- Automatically send emergency messages to predefined numbers using GSM technology as soon as an accident is detected.
- Ensure immediate emergency response and avoid delays in providing medical aid to accident victims.
- Develop a low-cost, reliable, and easy-to-implement embedded system using readily available hardware components.
- Combine the sensor, microcontroller, and GSM communication system into a single IoT platform for real-time monitoring of the driver's safety.

✂. LITERATURE SURVEY

1. Integrated Driver Safety Systems (2023-2025)

Recent research focuses on the integration of preventive (alcohol detection) and reactive (accident detection) systems in a single system. Integrated systems are more effective in both accident prevention and emergency response than standalone systems.

2. MEMS Accelerometer for Accident Detection (2023-2024)

MEMS accelerometers are used to monitor multi-axis acceleration. Sudden acceleration beyond certain thresholds indicates an accident. Research reveals that they are more accurate than vibration sensors and have fewer false alarms.

3. Alcohol Detection Using MQ-Series Sensors (2023-2024)

MQ-series sensors detect ethanol vapors by generating an analog signal proportional to alcohol concentration. Research reveals that they are effective, easy to use, and cost-effective for embedded driver monitoring systems.

4. Arduino Uno as Central Processing Unit (2023-2024)

Arduino Uno is preferred because of its low cost, open-source nature, and ease of programming. It receives data from sensors, makes decisions based on certain thresholds,

and controls outputs such as buzzers and GSM messages.

V. EXISTING SYSTEM

The existing driver safety systems are commonly used as independent systems like alcohol detection systems, accident detection systems, and mobile application-based safety systems. The alcohol detection system commonly employs breath sensors to detect the presence of alcohol and provides a local notification within the vehicle. The system is reliable and useful for preventing drunk driving, but it does not support driver identification and may cause false detection if passengers are intoxicated.

The accident detection system commonly employs vibration or shock sensors to detect accidents. Although the system is reliable and provides local notifications without internet connectivity, its accuracy is moderate since road bumps and potholes may cause false detection in normal conditions. Additionally, the system commonly works in a semi-automatic way and has low automation. Mobile application-based safety solutions make use of GPS and accelerometers in smartphones to track the movement of the vehicle. Although these systems are very flexible and easy to implement, their effectiveness is largely dependent on internet connectivity, positioning of the smartphone, and availability of the battery. Therefore, the effectiveness of these systems is relatively low in the event of a network outage.

VI. PROPOSED SYSTEM

The proposed system is an IoT-capable autonomous driver safety and emergency notification system designed using an Arduino microcontroller and GSM communication technology. The system is intended to solve two significant problems associated with road safety: preventing drunk driving and quickly notifying others in the event of an accident. The proposed system is capable of both preventive and emergency responses without the need for human intervention.

a) System Architecture

The proposed system consists of three main functional tiers.

i. Sensing Tier (Input): This tier is responsible for the continuous monitoring of the driver status and vehicle movement through an alcohol sensor and a MEMS accelerometer. The alcohol sensor is used to detect the presence of alcohol in the vicinity of the driver, which is unsafe for driving, while the MEMS accelerometer is used to measure multi-axis acceleration, which helps detect sudden impacts or collisions. The data from these sensors is used as input for the processing tier.

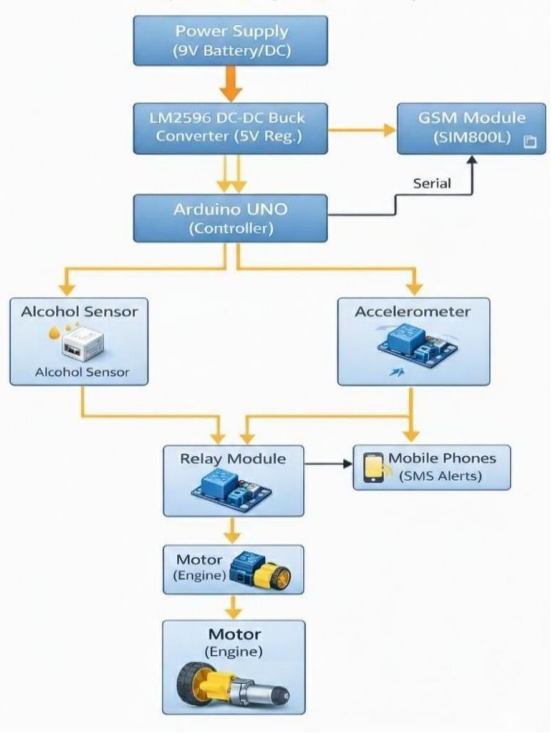

FIG 2 : BLOCK DIAGRAM OF THE PROPOSED SYSTEM

ii. Processing and Control Tier: This tier is based on the Arduino Uno microcontroller and serves as the decision-making component of the system. This tier continuously compares the sensor inputs with safety thresholds. Upon detecting excessive alcohol or unusual acceleration, the microcontroller is programmed to perform logic to generate

warnings, restrict engine starting, or send emergency notifications.

iii. Alerting and Communication Layer (Output): This layer is responsible for carrying out the response actions of the system. Local notifications using buzzers or LEDs are done to provide immediate in-car notifications. For remote notifications, the GSM module is used to automatically send SMS notifications to predefined emergency numbers, which can be done even when internet connectivity is not available.

b) Sensor Integration And Data Acquisition

The efficiency of the proposed system depends on the integration of multiple sensors with the central controller and the acquisition of real-time data.

★ Sensor Integration Methodology

Alcohol Sensor: The alcohol sensor generates an analog voltage proportional to the measured alcohol concentration. The output of the alcohol sensor is connected to one of the Arduino analog input pins (A0-A5), which enables precise measurement instead of binary detection. This improves decision-making by comparing the data with the threshold value.

MEMS Accelerometer: The MEMS accelerometer is utilized to detect sudden acceleration changes that indicate a possible collision event. The MEMS accelerometer is connected to the Arduino board using the I²C or analog pins depending on the type of sensor used. The MEMS accelerometer provides continuous multi-axis motion data.

★ Data Acquisition and Processing

The system uses a high-speed continuous polling process:

- **Continuous Polling Loop:** Arduino continuously acquires sensor data with a short delay.
- **Analog to Digital Conversion:** The onboard 10-bit ADC converts analog data to digital (0-1023)
- **Calibration and Analysis:**
  - ➢ Alcohol concentration is measured against a calibrated threshold.
  - ➢ Acceleration value is examined for unusual impact factors.
- **Threshold Logic Execution:**
  - ➢ Alcohol concentration above the threshold → warning / engine restriction.
  - ➢ Acceleration value above the threshold → accident notification through GSM.

Ⅴ. WORKING METHODOLOGY

The proposed IoT-based driver safety system works on the principle of continuous sensing, real-time processing, and automatic response. Once the system is turned ON, the LM2596 step-down voltage regulator regulates the input supply voltage and ensures a stable voltage supply to the Arduino Uno, sensors, and SIM800L GSM module.

The Arduino Uno then initializes all peripherals and goes into a continuous monitoring loop. It reads analog values from the alcohol sensor and converts them to digital values using the Arduino Uno's internal ADC. If the measured alcohol level exceeds the set threshold, the system generates warning or control responses to avoid dangerous driving.

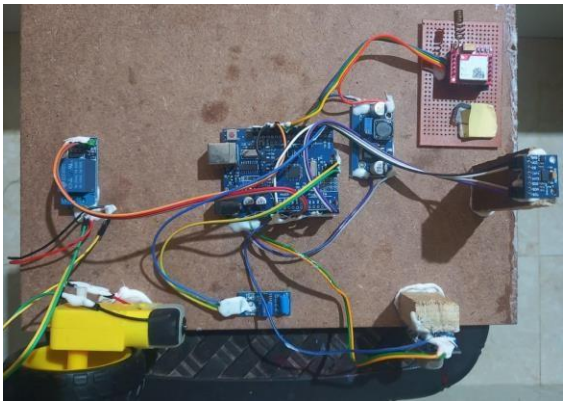

FIG 3 : HARDWARE MODEL

At the same time, the MEMS accelerometer continuously checks multi-axis acceleration of the vehicle. During normal driving, the acceleration levels are within safe limits. However, if sudden abnormal acceleration, which indicates a collision, is measured, the Arduino identifies it as an accident. When an accident is identified, the Arduino Uno communicates with the SIM800L GSM module through UART and sends AT

commands to automatically send emergency SMS notifications to pre-programmed numbers. This fully automated system enables fast accident detection, accurate remote notification, and improved driver safety without human intervention.

VI. RESULT

The IoT-based driver safety system was successfully implemented and tested, and it was able to meet its target of enhancing road safety by preventing drunk driving and accurately detecting accidents. The alcohol sensor was able to detect unsafe levels of alcohol accurately and send alerts within 5 seconds, thus preventing drunk driving. The MEMS accelerometer was able to accurately detect accidents without sending false alerts during normal driving conditions, and the emergency SMS alert was sent within 8-10 seconds.

The Arduino Uno board was able to make decisions efficiently in real time, and the GSM communication system was able to send alerts over long distances reliably even without internet connectivity. The LM2596 step-down converter was able to provide stable power supply during GSM transmission, thus preventing system failure.

The system was able to meet its target of being cost-effective, independent, and practical for real-time implementation. Future improvements, such as GPS and cloud integration, can be made to enhance the system and make it a complete intelligent vehicle safety system.

Abstract— traditional waste management system works on the basis of the daily plan that are inefficient and expensive. The current trash has also proven its inefficiency in the audience that people do not recycle the waste properly. With the development of the Internet of Things (IoT) and artificial intelligence (AI), the traditional waste management system can be replaced with a built -in smart sensor in the system to monitor real - time and provide the opportunity for better waste management. The purpose of this research is to develop a smart waste management system using LoRa - Communication Protocol and Tensorflow -based deep learning try. The LoRa sensor sends data and tensorflow real-time object detection and classification.Bin has several compartments to separate waste including metal, plastic, paper and general waste boxes controlled by Servo Motors. Object detection and waste classification The foremost object detection model is performed in the Tensorflow framework. This is an object detection model trained with garbage images to generate a frozen entrance graph used for object detection as the main treatment unit through a Arduino/ESP32. Ultrasonic sensor is installed in each waste compartment to monitor the level of waste filling. The GPS module is integrated to monitor the location and real time. LoRa communication protocol is used to transfer data about location, real-time and fillingKeywords:

Waste Management**,** Smart Waste Segregation**,** Sustainability, Automation, Image Classification

I.INTRODUCTION

Waste management has proved to be one of the most important global challenges due to rapid urbanization, population growth and industrialization. Incorrect disposal and poor separation of fixed waste has affected serious environmental issues such as landfills, soil and water pollution and greenhouse gas emissions. Traditional waste insulation methods are largely dependent on manual labor, which are inefficient, time consuming, and often expose workers under unaffected and dangerous conditions. In addition, the lack of systematic insulation reduces recycling efficiency and contributes to resource waste.

To remove these boundaries, there is an increasing requirement for automatic waste insulation systems that can ensure high efficiency, accuracy and stability. Recent advances in artificial intelligence (AI), Machine Learning (ML) and Computer Vision have provided innovative ways of classifying and processing waste materials with minimal human intervention. IoT-activated hardware components such as sensors, cameras and microcontrollers By mixing AI, waste insulation can be made smart, more reliable and scalable for applications in the real world.

This solution not only promotes stability and recycling efficiency, but also corresponds to the UN's goal for sustainable development (SDG 12): Responsible consumption and production. The proposed system is cost -effective, scalable and suitable for deployment in local communities, schools and public places, which contributes to a cleaner and green area.

II. LITERATURE REVIEW

Muthukumaran et al [1] Their system used AI-based image recognition and sensor monitoring to automate waste insulation and provide real-time without status warning. The study has shown that the Smart BIN system acquires high accuracy by improving the efficiency of waste management.

Atharva Kavade et al [2] His feature combined Yolov5 for automatic image classification and box separation with ESP32-cam and Arduino. The system classified waste to organic, biodegradable, plastic and metal, reflecting the effectiveness of AI and data vision for the separation of real-time waste.

Teah Ji Sheng and Mohammad Shahidul Islam [3] (2022) developed an IoT-based smart waste management system using LoRa and TensorFlow Deep Learning models published in the International Journal of Scientific and Engineering Research (IJser). His model provided a low effect and long - distance communication solution for real-time monitoring of waste levels using intensive learning. This system was effective in monitoring urban waste, which improves operating cost efficiency.

Chithirai Selvan S [4] (2023) proposed a fully automated waste settlement and management system using AI, ML and IoT, published in the International Journal for Research Trends and Innovation (IJRTI). This task is an integrated sensor with Arduino to detect fill levels on the trash can, which enables IoT-based communication. The system helped to reduce environmental hazards by providing real-time warning and automatic insulation.

Mohammad Haleem Mohammad Noor [5] (2023) conducted a detection and classification survey using Deep Learning, published in the International Journal of Research Publication and Reviews (IJRPR). The study analyzed models such as CNN, Yolo and MobileNet for automated waste identification and classification. It concluded that models such as Yolo and CNN provide promising results for the classification of real time with high accuracy than other approaches.

MD. Shahiar Nafiz et al [6] His system implemented a motor motor mechanism and integrated Convowaste CNN model with GSM-based monitoring through an Android app. It gained 98% accuracy in classifying six categories of waste, proving its ability to support the goals of circular economy.

Finally, Gary White et al [7] The study suggested a Yolov 3-based waste identification system that was trained on taco datasets for smart waste monitoring. The system demonstrated successful classification functions in the environment, making it suitable for scalable smart waste management.

Lahoti et al [8] created a low-cost waste sorting prototype that combines YOLOv5-based computer vision with a 3D-printed robotic arm on a Raspberry Pi. The system sorts six waste streams and is able to sort with around ~80% accuracy in a controlled setting. The strengths of this work is in the demonstration of an entire system and a relatively inexpensive system made from lightweight and accessible components that may allow for replication in research and education. this work is still aligned with research in the field of AI recycled sorting pathways but has not moved beyond a prototype, there remains challenges for broader datasets, challenges with robust grasping, and lack of field trials which can all lead to the industrial adoption.

Ramsurrun et al [9] developed a recyclable waste classification system using deep learning and computer vision to identify items including glass, metal, plastic, and paper. The model was based upon a CNN architecture, and can be generally considered to demonstrate acceptable classification accuracy on the dataset they created, to support the use of AI in the classification and separation of recyclable waste. Moreover, their work adds to a growing body of evidence in the emergent area of image-based deep learning in waste management, despite the research being limited to classification and investigation of neither detection or robotic actuation.

Ba Alawi et al [10] examined solid waste classification using deep learning and compared several CNN architectures including AlexNet, DenseNet121 and SqueezeNet. The results indicated that DenseNet121 had the best accuracy and reinforces the promise of CNN-based models for the classification of images of solid waste. The scope of their work was with controlled datasets and only classification, so their work has yet to be transferred to the real world or robotic sorting, so their work is still in an early stage toward the application of deep learning in waste management.

Majchrowska et al [11] addressed the challenge of detecting and classifying waste in both natural environments and urban settings with a two-stage pipeline. They utilized EfficientDet-D2 for localization and EfficientNet-B2 for classification. They established a standardized unified datasets benchmark across numerous datasets and also explored a semi-supervised learning approach to facilitate outcomes, achieving 70% detection precision and 75% classification accuracy. The research extended beyond lab-based control

environments to cluttered real-world scenes and represented an important step toward a functional solution in real AI waste detection solutions.

Kumsetty et al [12] created TrashBox, a framework designed for waste detection and waste classification using quantum transfer learning for improved recognition performances. The authors trained quantum enhanced models on a standard dump image datasets with comparable accuracy to classical deep learning baselines. This work shows possible for quantum machine learning for sustainable AI applications while all experiments investigated were prototype development with limitations to the hardware capabilities of a specific device and dataset size.

Lynch [13] introduced OpenLitterMap.com, a crowdsourced open-data platform for mapping plastic pollution. The platform incorporates a reward system based on blockchain technology (called Littercoin) to motivate users and inspire engagement. In the platform, users from around the globe can contribute geotagged litter-data, and in doing so, create an open-access dataset of plastic waste in the environment. This work is important because it connects issues related to citizen science, open geospatial data, and blockchain technology to address the challenges surrounding plastic pollution. However, it does rely on communities to contribute data that maintains quality and consistency.

Wang et al [14] conduct a research study on a multi-level segmentation approach to waste object recognition from image data from sensors. Their proposed step-by-step approach uses first a coarse object recognition followed by a segmentation that refines the object boundaries so it is identifiable from the background and other sources or types of pollution. The results from the experiments provide evidence that the approach works well and the multi-level design provides higher quality segmentation, compared to a single stage design in a waste object detection task. The hierarchical design provides better segmentation because of the three dimensional segmentation, which could have some useful applications in the areas of waste management.

Patil [15] and colleagues used deep learning methods to develop an application that identifies waste automatically. They created an application that is simple to use and is efficient to differentiate between recyclable and non-recyclable material. The study presented a potential use for AI-based waste classifiers for use; however, the study did focus only on classification and did not deploy any robotics, nor did it centralize the sorting of waste.

III. EXISTING SYSTEM

1. Insufficient Training Data The model has been trained on just 1,500 waste samples, which cannot possibly encapsulate the range of waste types found in the real world.
2. Training Results and Low Accuracy With an accuracy on training of only 71.8%, underfitting seems present, meaning an accurate decision has not been fully learned in classification on image placement.
3. Night time Recognition The visibility of the camera is limited at night, which restricts this system in detection in low-light conditions.
4. Battery Replacement A single replaceable battery is utilized for the power supply of the project and in turn, time in operation is limited and continuity of operation may not occur.

IV. PROPOSED SYSTEM

A.SYSTEM ARCHITECTURE

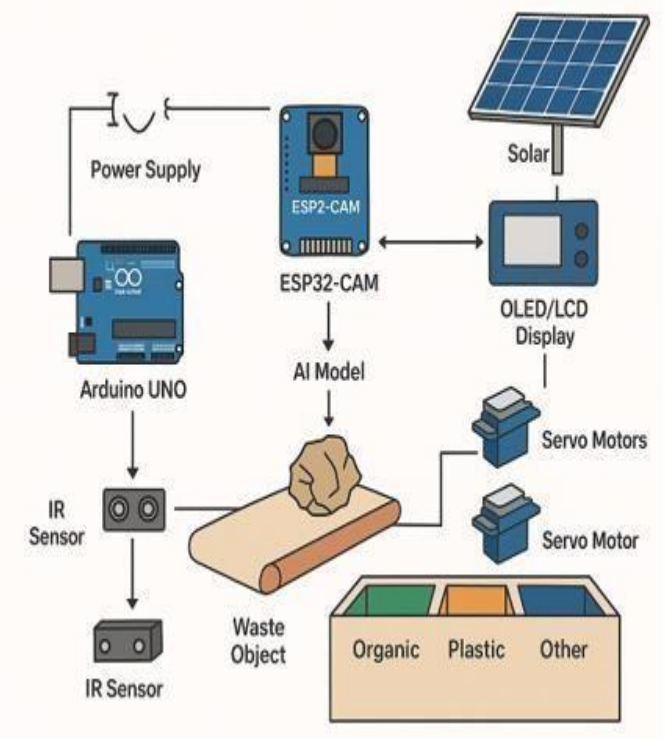

Fig.1. AI-BASED SMART WASTE SEGREGATOR FOR SUSTAINABLE WASTE MANAGEMENT

The smart waste segregators are enhanced with AI intelligence, so that they can work as a united system of hardware and software modules for easy, smart waste segregation modes. Part of the system's one-of-a-kind hardware is the AI image classifying module, which recognizes and classifies the waste, so that it can be accurately sorted at the bins. This hardware (IR Sensors, conveyor, and servo motors) physically separates the waste and directs it to the appropriate container in conjunction with the AI.

The Smart Waste Flush System has a hybrid energy system with solar panels powered directly with a power outlet and battery backup system. The hybrid energy system provides resiliency from an interruption of power while supporting consistent operation of the system in both urban and rural environments. Also, the capability of being powered by renewable energy reduces operational costs and is environmentally sound. The hybrid power system is also integrated with automation and AI intelligence with flexible supply management demonstrate to be demonstrative smart solutions to modern waste management problems to help promote clean environments and operational efficiencies for recycling processes. Initially, a waste object is detected by the IR sensor from the carrier. As soon as it detects the object, the ESP32-CAM module will capture the waste object's picture for classification. The image will be sent to AI model that has been trained using a fixed neural network (CNN) to classify the waste into organic, plastic or other (metal/paper/glass) types.

Accuracy (%)= Total Predictions / Number of Correct Predictions ×100

In this intelligent waste separation system, a central control unit is comprised of the microcontroller (Arduino Uno) that mediates the system's hardware and software aspects. The microcontroller receives input signals from the IR sensors that inform the microcontroller if waste materials are present and what type of waste it is, the microcontroller also communicates with the ESP32-CAM module which will capture and transfer images to the microcontroller and performs image processing. An artificial intelligence (AI) classification model will process and analyze image taken by the camera (or camera module) and provide historical information, classification, and sorting on the waste detected. The Arduino Uno will take this classification and control the servo motors that will then mechanically move the conveyor belt coverings, the carrier board, flaps, or similar directing waste items to the proper bins. This mechanical movement is needed to reduce contamination and promote better sorting utility.

It is also designed with a dynamic OLED/LCD display to provide the ability to receive dynamic feedback in real-time. The display includes data such as what the item was identified as being waste, operation state, and energy levels, which will encourage interaction and awareness of the system by the user. The system is an integrated approach to waste management, combining AI-based classification, IoT-enabled sensing and robotic actuating to deliver a seamless, intelligent and extensible process of waste management. The system architecture is robust and energy-efficient, and can be adapted for a variety of deployment mechanisms, both urban and rural. The combination of intelligent sensing, automated (robotic) control, and user monitoring has created a modern, trusted waste management process.

```
def preprocess_img(img_path):
img = image.load_img(img_path, target_size=(128, 128))
img_array = image.img_to_array(img)
img_array = np.expand_dims(img_array, axis=0)
img_array = img_array / 255.0
return img_array
```

B. MODULE DESCRIPTION

The system being described is made up of 7 modules.
MODULE1:Power Supply & Solar Module
MODULE2: IR Sensor Module
MODULE3: ESP32-CAM Module
MODULE4: AI Model (Image Classification)
MODULE5: Arduino UNO / Microcontroller Module
MODULE6: Servo Motor & Conveyor Mechanism
MODULE7: OLED/LCD Display

V. RESULTS AND DISCUSSION

A.IMPLEMENTATION DETAILS

The hardware configuration of the proposed AI-based waste insulation system integrates several main components to achieve efficient and automatic operations. As a primary vision component of the entire unit, ESP32-CAM will be used to take real time images of the waste unit and treated later for classification. Utilizing a solar panel with battery back-up allows for renewable energy and more sustainable operations in areas of low power. Servo Motors allow for the physical insulation of the waste, as well as the opening of the bin room that had been classified after classification. To enhance monitoring in an innovative way, ultrasound sensor or IR sensor can detect fill levels and the vicinity of the user. In addition, temperature and humidity are installed inside the sensor box to monitor environmental safety, preventing health hazards such as Odor or microbial development. The

core of the hardware system is microcontroller (Arduino or ESP32), which coordinates the input and output signals, manages the sensor data and controls the servo system.

The software architecture focuses on AI-operated classification and control logic. A neural network (CNN) is trained on waste images to classify materials in categories such as plastic, glass, metal or paper. To ensure high accuracy, images are prepared using OpenCV with python, which increases image quality and extracts useful functions before classification. When the waste type is identified, the motor control argument removes - the program programmed in the microcontroller - the right servomotor removes appropriate mechanical effect. This uninterrupted integration of AI and control algorithms ensures that waste is automatically sorted into proper garbage reduces manual intervention and repair

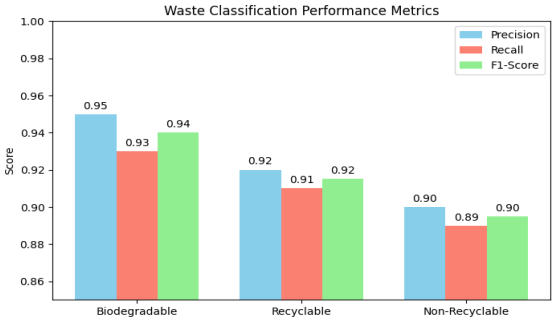

Fig.2.Waste classification performance metrics

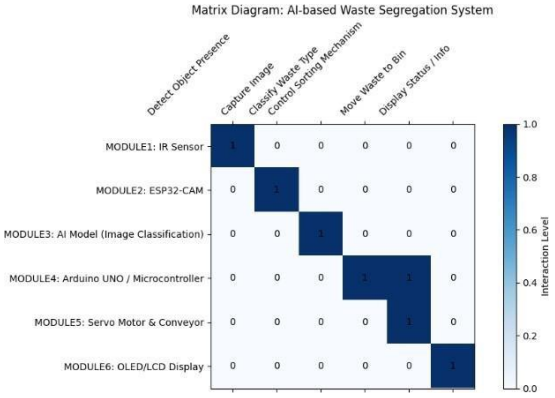

Fig.3.Matrix diagram for which module perform which function

Conclusion And Future Scope

Future Scope

• The future for handling waste separation with advancement and adoption of AI-based systems is heavy.
• These systems, operated by AI algorithms and integrated with IoT technologies.
• It provides vision of very efficient, automated and data -driven waste management practices.

Conclusion

The proposed Smart Waste Segregation System using artificial intelligence aims to ease the growing complexity of waste management in modern platforms with a highly efficient, inexpensive, and robust solution with the automation of separating waste into distinct categories, which include organic, plastic, and others. The system contains ESP32-CAM modules to provide real-time imaging to an Artificial Intelligence Convolutional Neural Network (CNN) for an accurate classification. The detection and identification of waste items are done using IR sensors generating information that is received and processed by an Arduino UNO microcontroller that acts as the central controller. After classification using AI, the microcontroller effectively uses the provided information to non-mechanically sort disposed waste into the appropriate garbage bins using servo motors and mechanical actuators with a motor-driven mechanical gate. An OLED/LCD Monitor will provide feedback in real-time indicating the class of waste, system status, and contact/charge levels while providing engagement and monitoring the system's current status. Using intelligent sensor systems, mechanical systems, and AI classification the system proposed in this concept supports reliable, scalable, and energy efficient operation, which can satisfy the wants of urban and rural environments concerned with sustainable management of modern waste all while being supported with intelligent solutions using AI.

***Abstract*—A fresh tide of plastic floods the seas every twelve months, though plenty vanishes quietly into rivers. Swept along by strange tides, tiny pieces spread wide, dodging any clear count. Old methods fall short - slow, pricey, limited in reach. Rather than stick to them, scientists test a new tool. From above, orbiting eyes scan vast ocean surfaces, even as underwater streams steer trash on hidden paths. When the world shifts nonstop, information shapes itself into clearer forms - just as ripples sync without planning. Through links that grow like thought patterns, understanding updates when fresh clues appear. As plastic gathers in clusters, warnings emerge quicker than before. Light bounces strangely off junk on water, stripping away shine to reveal what lies beneath. Drifting scraps ride ocean flows - models follow those paths in reverse, tying tainted waters back to river sources. Across borders, researchers team up - boosting precision while keeping private details locked away, aiding ocean recovery behind the scenes. Debris rides currents; equations break it down.**

Index Terms*— *Microplastic prediction; Satellite remote sensing; CNN-LSTM; Spectral anomaly fingerprinting; Lagrangian drift simulation; Federated learning; Marine pollution; Ocean monitoring; Deep learning; Environmental AI.

I. INTRODUCTION

A truth rarely mentioned? The amount of microplastic in the sea remains unclear. Estimates exist. So do simulations. A couple thousand data spots dot an expanse of saltwater spanning most of Earth's surface. Picture grasping rush hour chaos after chatting with just a trio at one transit hub. Back in 2022, plastic output topped 400 million tonnes. Of that amount, roughly 8 to 10 million finds its way into oceans annually. Sunlight weakens what lands there, while waves chop it down further — into specks less than 5mm across, even bits below one micrometer. These tiny fragments ride water flows like invisible drifters, then slip inside plankton. From there, they climb higher through sea life meals until traces turn up where we least expect: inside our own bloodstream and lungs. Surprising? Not really — it's been confirmed already [1], [2].

Here's why things remain unclear: missing gear, not care. Hauling a boat out just to scoop up seawater, later poring over results using slow lab scans, simply cannot cover vast seas. A fresh path had to show up. Right now, scanning from afar while teaching computers to spot patterns stands as the leading option available.

Some issues this project tackles: vast stretches stay untouched — wide sea surfaces, nearly all rivers across Southeast Asia, even the icy waters circling Antarctica. Detection always comes into view after the fact, weeks after plastic has already settled. A single system links none of the data — satellite groups, ocean researchers, campus scientists, aid workers all gather facts solo. And even when pollution is spotted, its origins stay hidden — pinning a garbage patch to a river in India months back remains nearly impossible [3].

What you get includes six parts working together for the first time ever. One piece links to another, each playing its role without extra weight. Inside, components shift smoothly when needed. Each section fits where it should, nothing forced. Movement happens only when required, staying still otherwise. The whole thing holds steady during use, yet adjusts easily

1) A flicker, unnoticed at first, slips through the numbers machines collect. This method spots hints behaving like synthetic material, uncovering order in what looked like randomness.

2) A fresh forecast rolls out every three days. This one follows dirty bits floating through air currents. Motion rules of liquids guide the model. It starts up right after grime shows on sensors. Never pauses till told.

3) A stain on the land points backward, tracing steps not taken but carried, by bits dragged along water's path. Where it gathers now was not its birth. Flow marks cut across ground, hinting at origin - could be a streambed, could be sand scarred by tides.

4) Out on each device, learning happens locally - models grow smarter while information stays put. Instead of shifting files around, updates travel between nodes quietly. This setup skips the need to gather personal details into one spot. Progress spreads through cooperation, yet every system holds onto its own bits. Training improves everywhere because insights merge minus the transfer.

5) Where nature struggles most, pollution hits fiercer. That's when BIO shifts its alerts - tuned to fragile spots first.

6) Pollution levels shift over time across ocean zones - PITTA tracks these changes inside each grid block. Patterns emerge slowly, yet every cell tells its own story through years of data flow. Instead of broad claims, it focuses on gradual shifts hidden beneath surface numbers. Each measurement point adapts to timing quirks, revealing what steady observation can uncover. Long spans of record-keeping feed into how trends take shape within the system.

II. RELATED WORK

A. Remote Sensing: What It Reveals and What Stays Hidden

High up above the planet, satellites pick up big blobs of drifting plastic - ones wide enough to notice, like the huge spirals far out in the Pacific Ocean. Instruments including HYPSO-1 and DESIS show that dense patches of waste alter light in ways distinct from regular ocean water [4]. But there's a snag: small fragments seldom bunch together clearly. Scattered across currents, usually under the waves, their weak signal drowns in background noise - flickering plankton, cloudy sediments, sunlit chop. At present, orbiting sensors fail to detect individual specks. Picture this: waves shifting, air curling along the surface, heat slipping sideways over open water. Out of these hints, something like a guess takes shape - uncertain, but shaped by how things actually fall into place [5].

B. Machine Learning Methods Used Until Now

Near coasts, some tree-based systems using ocean hues get about 70 to 75 percent of identifications correct - useful, but not enough for practical decisions [6]. When smart nets study Sentinel-2 images, accuracy creeps toward 80 in specific situations [7]. Slipping past the net? Timing. Many approaches freeze on single moments, although stained zones drift over time. Earlier tools based on memory circuits can follow shifts while estimating flows or muddiness, however none blend that sense of change with sky-eye photos to spot small plastic scraps adrift.

C. Physics-Based Drift Models

Something triggers the next step automatically around here. A device sees an anomaly, which leads to water motion simulations kicking in without help. Tools like OceanParcels trace drifting objects using real ocean currents with strong precision [8]. When set up carefully by experienced users, they work well. Still, these systems run separately - no internet connection, no automatic refreshes, no clever code reacting to shifts. The gap between sensor alerts and modeled flow predictions gets closed here, connecting observation moments directly to simulation responses

D. Federated Learning in Distributed Systems

Federated learning — Now imagine devices spread far apart learning together without sending sensitive details. Instead they exchange small clues about what changed - like whispers between stations. This trick already works in hospitals and banks where secrecy matters just as much [9]. Trying it out on sea sensors? That part is fresh territory. FLNA leads here, building a system where water monitors talk through gradients alone. Even if labs keep their numbers close, they can feed into one big picture of the oceans.

III. SYSTEM ARCHITECTURE

A. The Big Picture

Above all sits a quiet hum of foresight. Before that, models weave what they've learned from clean streams below. Earlier still, messy data finds order here. Below ground level, eyes in the sky feed fresh pulses every few minutes. Not far after, early signs begin to align on their own

Something feeds the level above, slow but steady. An alert shows, then simulations start right away, tied to actions that fit. Right at the front, what's happening gets sorted on screen - simple layouts folks really work with.

Pictures arrive from space, while ocean motion adds its rhythm. Sea buoys send fresh readings before anyone even asks. Local watchers file what they see, grounding guesses in reality. Air pressure shifts weave into the mix without delay. Lab-confirmed samples plug into the stream like puzzle pieces fitting late at night. Every sixth hour, the system draws a new forecast - no longer stuck waiting. Because everything flows together, the danger map never stops changing.

B. Five System Modules

Module 1 — Data Ingestion: Now and then, fresh batches come in from Copernicus, NOAA, ECMWF, along with GloFAS, pulled by scheduled triggers. Once they land, each one faces a quick scan for usual ranges before moving on. Right at arrival, every piece slips into a record, simply because. Should any chunk be absent - perhaps cloud cover interfered or a satellite missed its turn - the gap rings a bell straight away. To bridge those breaks, nearby moments from past and future steps step in quietly. Fresh feeds arrive every few hours - snapshots from orbit, shifts in ocean currents, air pressure trends, constant signals from floating monitors, verified lab results, along with notes jotted down by people on shore. Because everything lines up at once, forecasts now form twice as fast as before. That steady pulse keeps the danger chart alive, changing without pause

.Module 2 — Preprocessing: Cloud : Out into the workflow steps a cloud filter using Sentinel-2's SCL layer. Following that, subtle visual hiccups fade out via Sen2Cor corrections. One fixed map frame pulls every image into place afterward. Sliding three-week mean values stretch each light frequency range next. Between sensor timestamps, nature measurements grow extra dots till timing clicks perfectly with snapshots.

Module 3 — CNN-LSTM Engine: Halfway through, connections merge when image data travels via convolution layers while temperature logs advance slowly in sequence units. Sight paths meet environmental timelines inside a joint zone where meaning mixes before decisions arise. A solitary warning grade appears, formed equally by sky views and past storms. From dual origins it grows - cameras feed one branch, sensors the other.

Module 4 — Simulation and Attribution: From clearly marked zones, the LPDS advances into future moments. In reverse, PSAG follows paths backward instead. Once Module 3 detects a signal that meets its threshold, both systems activate immediately - no waiting.

Module 5 — Dashboard: A flicker of activity builds out of sight. Where problems spark, colored spots jump into frame. Decisions form depending on signals close by. Movement trends rise or fall as seconds pass. One shade stands for one

type of impact on life. When attention is needed fast, pings show up.

IV. DATA SOURCES AND GROUND TRUTH

A. Satellite Imagery

Every few days, fresh images from Sentinel-2 offer fine clarity, making it a top pick. If gaps appear due to delays, MODIS fills the gap instead. After dark, VIIRS detects glowing areas - often linked to coastal crowds and vessels at sea, both clues pointing to plastic reaching waterways. Together, the satellites form this setup as in Table I.

TABLE I

Satellite Data Sources and Key Parameters

Satellite	Resolution	Key Bands	Revisit
Sentinel-2 MSI	10–60 m	SWIR B11/B12, NIR, Red Edge	5 days
MODIS Terra/Aqua	250–1000 m	Ocean Color, SST	Daily
Landsat-8/9 OLI	30 m	Coastal Aerosol, SWIR	16 days
VIIRS (Suomi NPP)	375 m	Night Lights, SST	Daily

B. Oceanographic Data

Over the ocean waves, NOAA HYCOM reveals currents - speed and direction shifting daily through precise 1/12° grids. Instead of static snapshots, each update unfolds new patterns beneath sunlight-glazed surfaces. Meanwhile, Copernicus follows swelling heights and salty shifts, layer by layer down below. As weeks pass, those depths tell stories of change held in water weights. Beneath everything, GEBCO charts seabed shapes - rises and trenches guiding where waters collide. Because terrain steers flow, certain spots gather converging streams more often. Scattered throughout, about 4,000 free-drifting Argo floats record onboard readings: heat and salt pulled straight from deep drifts.

C. Meteorological Data

Every three months, ECMWF ERA5 gathers details like wind split into sideways and upward pushes, how much it rains, along with air weight - laid out point by point across a map spaced at 0.25-degree steps. When showers run off land, they drag plastic bits toward creeks - here, GPM IMERG jumps in, watching rainfall closely as it happens, offering fresh views on wet zones so flow routes show up fast. Rather than stretch waits to days on end, results appear just after a few hours pass [10].

D. Ground Truth Data

Out there, data on microplastics isn't handed out freely - it's scattered, spotty, stretched across places without much pattern. Pulling from three spots gives what we've got: one comes by way of the TARA Ocean Expeditions, dragging nets behind ships while marking where each sample lands on a map; another taps into EMODnet, Europe's underwater tracking web; then there's The Ocean Cleanup crew jotting down every catch they pull from the North Pacific swirl. When laid side by side, those pools add up to roughly fifteen thousand points tied to exact locations - just solid enough to teach models but too slim to rely on alone, which nudges things toward needing smarter filling-in tricks.

V. NOVEL TECHNICAL COMPONENTS

A. Spectral Anomaly Fingerprinting (SAF)

Pieces of plastic too small to see clearly from above? Not simple. The ocean carries loads of things messing up light readings - floating algae, decayed plant goop, specks of dirt drifting by. A rough setup taught poorly guesses seaweed whenever real plastic could be near.

Here is how SAF operates. Instead of labeling images as plastic or non-plastic, it studies what clean water typically looks like across specific light ranges - particularly in shortwave infrared areas such as B11 (1610 nm) and B12 (2190 nm) captured by Sentinel-2, where plastic interacts with light in a distinct manner [11]. Using thousands of pixel samples confirmed debris-free over three years, an autoencoder builds a model of this standard pattern. As new imagery comes in, each point in the picture is assessed according to how much it strays from that baseline in these critical bands, after correcting for expected interference.

Here's a score from zero to one telling how probable plastic is in any given place - called the Plastic Probability Index. High numbers do not mean plastic has been found; they signal odd patterns in light similar to those tied to plastic debris. What helps? The system adapts when seasons change, meaning a sudden burst of algae during warm months won't mistakenly trigger false signals down the line.

B. Lagrangian Particle Drift Simulator (LPDS)

When the prediction finds a danger zone, focus turns to paths pollutants could follow. Moving into view, a thousand virtual markers get released by LPDS, carried forward using real ocean currents from HYCOM data. Their movement picks up small tugs often ignored - wave-driven drift joins a surface shove matching roughly 3 percent of wind force [12].

A thousand particles instead of just one reveal patterns over time. Where things could go shows up across the full span — day one, two, even three. Darker patches on the map show where more of them wind up clustering together. One overlooked fact: tiny plastic bits do not float forever. As algae and microbes slowly coat each piece, the material grows heavier. LPDS accounts for this using a basic observed rule tied to both plastic kind and water warmth at the surface. Boats meant for cleanup can then wait just before polluted areas move in, instead of racing after damage already spread.

C. Plastic Source Attribution Graph (PSAG)

Forward motion defines how LPDS moves through time. In contrast, PSAG steps in reverse. If a hotspot shows up, PSAG checks the GloFAS river flow data while launching a backward path model — drop imaginary bits into that sea spot

then move them back in time following old ocean flows. From there, see where those pieces gather — rivers or shore areas alike [13].

A single path begins at each warm sea spot, branching toward likely starting points like river exits or harbors based on how often trash moves that way and how much flows out. What comes out is a line-up of possible sources tied to those hotspots — each tagged with a number showing how strongly it's linked. It's meant to work with likelihoods, never certainties. A solid guess — say 60 to 70 percent sure — can still shift talks between countries forward, offering a starting point where silence once stood.

D. Federated Learning Node Architecture (FLNA)

Not every country feels comfortable sharing what their sensors pick up at sea. Ships exploring waters, stations on shore, plus floating devices out in the open rely on information that crosses borders quietly. Still, handing over unprocessed numbers often gets stuck in legal tangles [9].

FLNA skips full data sharing. Instead, every device learns from its own examples, then passes just the tweaks — never the original records — up to the main hub. That central point gathers adjustments through a special averaging method. A single research post in Indonesia might feed data into the system while sensors floating off Norway add their readings too — yet neither sees what the other sends. Low communication needs mean just hundreds of megabytes per round, and even spotty links work fine.

E. Biodiversity Impact Overlay (BIO)

Not everything loud shines the strongest. Where salt air never stops turning, risk often hides beneath stillness. Close by, along thin ridges of chalk-like rock sheltering uncommon beings, the pressure builds quietly. Pollution trails tied to animal locations pulled from IUCN data, alongside real-world observations mapped through OBIS, form the backbone of BIO's method. In each place flagged as dangerous, a figure emerges - the Species Vulnerability Score. This value climbs higher wherever filth piles up among thick clusters of creatures, more so should threatened kinds linger there or delicate habitats such as reefs and underwater meadows take root.

A place teeming with fragile life climbs higher when both sites suffer equal contamination. Priority shifts - not just mapping filth, but guarding vital ecosystems. Protection slips into focus, prevention taking root behind the scenes. Detection numbers might hold steady, yet the aim reshapes itself quietly.

F. Pollution Intensity Temporal Trend Analyzer (PITTA)

What comes later can matter. Yet spotting slow drifts over weeks, even months, sometimes slips through the cracks during monitoring. Each month, PITTA refreshes pollution figures on ocean sections - one degree wide each way. Since values rarely spread smooth, it leans on a method named Mann-Kendall - this one handles messy flows better than most [14]. Checking how things change shows if they're improving, holding steady, drifting down, or jumping up quickly. It's not only about which way things move, yet also how fast - a gradual drop feels different than a sudden spike.

A warning flashes the moment danger strikes a watched area. Because of this alert, environmental crews can move fast to lock down support money - well ahead of headlines catching wind.

VI. MACHINE LEARNING ARCHITECTURE

A. Input Feature Set

The full input feature configuration feeding the model is shown in Table II.

TABLE II

Input Feature Categories and Sources

Category	Features	Source
Spectral	B2–B12 reflectances, PPI score	Sentinel-2 + SAF
Thermal	SST anomaly vs. 3-yr mean	MODIS/VIIRS
Biological	Chlorophyll-a, CDOM, turbidity	MODIS Ocean Color
Oceanographic	Current speed/dir., Stokes drift, MLD	HYCOM / CMEMS
Meteorological	Wind U/V, precipitation, pressure	ERA5
Contextual	Day-of-year, ENSO index, tidal phase	Multi-source

B. Architecture Details

A single patch of terrain appears as a grid sixty-four squares wide and tall, every cell storing one of twelve hues recorded by Sentinel-2 eyes in space. Rather than crafting intelligence fresh, the method uses ResNet-18, previously trained on BigEarthNet - a massive set of labeled planetary images [15]. The final stages that make choices get replaced, fine-tuned to match the current task. From this emerges a sequence of two hundred fifty-six values capturing the layout hidden within that tiny frame.

A month's worth of information feeds into the machine - ocean motion, heat in the air, signals of storms, every kind linked to a fixed point on land. Since patterns appear not just in past hints but also in what follows, the system looks both ahead and behind in time. Nested within sit two layers of learning units, each equipped with 128 nodes, adjusted to notice changes over many days. Out of this grows a snapshot made of 128 values, showing how conditions have changed around that location.

A single stream forms when 256-dimensional space details meet the 128-part timeline input, merged by connection. Through two thick layers it travels, where every step drops three tenths of values at random. Out comes a score between nothing and one - pollution risk - with an extra span around it revealing confidence, shaped by running dropout many times while evaluating.

C. Training Details

Some 15,000 geotagged data points from TARA, EMODnet, and Ocean Cleanup form the base of the training collection. Since polluted patches appear rarely, the system uses Focal Loss to shift focus - prioritizing ambiguous or complex regions rather than spending effort on obvious, untouched water stretches.

Starting with AdamW as the pick for optimization, the process begins at a learning rate of 0.001. This number eases lower over fifty cycles, shaped softly by cosine decay - gentle, consistent, never sudden. Divisions form based on sea zones rather than randomness, making sure training and evaluation sets stay apart. If partitions were shuffled freely, neighboring spots could appear in both, giving false signs of progress. Because ocean basins form physical barriers, they limit signal flow between regions. Reaching an F1 higher than 0.85 matters, just as hitting AUC-ROC past 0.90 does within those zones.

VII. IMPLEMENTATION

A full overview of the tech setup appears in Table III. Starting with a new satellite image, the process kicks off automatically - information goes right into preparation, no pauses. After cleaning, it shifts directly to examination, nothing held back. If outcomes point one way, LPDS activates; if another, control passes to PSAG. Updates stream in real time to the screen. Once set up, no touching needed at any point.

TABLE III

System Implementation Stack

Component	Technology
Satellite Processing	Google Earth Engine, GDAL, Rasterio
ML Framework	PyTorch + HuggingFace pretrained backbones
Drift Simulation	OceanParcels (custom), NumPy
Source Attribution	NetworkX, Neo4j
Federated Learning	Flower (flwr)
Geospatial Backend	PostGIS, GeoPandas
API Layer	FastAPI + Celery
Dashboard Frontend	React + Deck.gl
Deployment	Docker + Kubernetes on GCP

VIII. EXPECTED RESULTS AND EVALUATION

Check Table IV for how well things performed on every test. Coastal areas get mapped at ten-meter points. Open ocean uses two hundred fifty. Updates come every six hours. The forecast runs out to seventy-two. False alerts happen less than once in ten tries. Most often, the leading three suppliers agree seven times in ten.

TABLE IV

Target Performance Metrics

Metric	Target Value
Prediction F1-Score	> 0.85
AUC-ROC	> 0.90
Coastal Spatial Resolution	10 m
Open Ocean Resolution	250 m
Prediction Update Frequency	Every 6 hours
Drift Forecast Horizon	72 hours
False Positive Rate	< 10%
Source Attribution (Top-3)	> 70% accuracy

In 72 hours - that's when our tool proves most useful. Cleanup boats get a window, so they can move into place before oil hits, not after it washes up. Coastal crews also benefit, shifting earlier because forecasts arrive sooner. Pinpointing origins remains tough though, messy even under ideal conditions. Seventy percent success rate for spotting likely sources? That number fits the challenge. Chaos at sea blurs clues, limits certainty. Guesswork fades when data steps in, quietly filling gapsocean systems — not a strong guarantee, but a starting framework where no data currently exists

IX. APPLICATIONS AND TARGET USERS

Not everything on water fits here. Made just for certain jobs Alerts happen automatically, so teams skip scanning satellite pictures by hand. When conditions change, updates arrive fast - no waiting on manual checks. These systems watch the environment nonstop, flagging shifts as they appear. Staff stay informed through timely notifications instead of routine image reviews. Monitoring runs quietly in the background, freeing up hours once spent on visual inspections.

Starting down at the waterline, efforts like The Ocean Cleanup build around motion patterns - guessing tomorrow's junk locations often counts more than photographing floating bits now. Because flow forecasts shape smarter actions, insight into drift tends to outweigh static coordinates. What moves reveals more when timing aligns with trajectory.

Not many protect delicate sea zones. Yet certain scientists study marine creatures day after day, noticing shifts that slip past most eyes.

When pollution crosses borders, leaders must trace where it started before talks can move forward. One country might blame another, but proof of origin shapes the discussion. Where smoke begins affects who takes responsibility. Disputes grow when emissions travel far from their starting point. Leaders need clear links between cause and location to make progress.

Scientists seeking reliable microplastic data can tap into an API that delivers verified, regularly refreshed information. Access rolls out smoothly for those focused on current environmental metrics. Updates flow without delay, keeping pace with new findings. The system supports steady integration into ongoing research workflows. Data quality stays high through consistent validation checks. Anyone tracking tiny plastic particles benefits from this live feed approach.

X. LIMITATIONS

Most studies happen in the North Atlantic and North Pacific, so that's where the training data leans. Because of this imbalance, performance may drop when applying the model to the Indian Ocean or Southern Ocean at first. To help balance things later, teams working there will be invited to join early on.

Maybe it points a finger, but that does not mean guilt. Guessing where something came from works on odds, not certainties. Decisions in court or talks between nations need more than just this. It suggests possibilities — never slams down conclusions. A tool for asking questions, never for ending them.

Federated learning keeps data more private, yet still leaves some risk — gradients might reveal details when attacked. Noise from differential privacy should show up in later versions. Funding future work happens through paid subscriptions — access to hosted tools and APIs sits behind that paywall. Yet everything core remains free: the code, the trained models, the full process used to build them. Science lives out in the open, even as services grow around it

XI. CONCLUSION AND FUTURE WORK

A fresh review of this work reveals something straightforward: progress slips away if we do not monitor - though vessels and experiments inch forward by themselves. Above it all, orbiting eyes catch every stretch of land below. Through smart algorithms, order appears within tangled data chaos. Physics-based models give clues about where contamination will drift. Once linked together, gaps in awareness fade fast.

Our product does not solve plastic pollution. Yet it brings clear sight - making messy problems possible to count. As numbers get better, actions move toward the places that need help. This shifts how every dollar behaves, reaching farther even when budgets stay flat.

Now picture tiny drones bobbing across wide seas, shifting course when signals tell them to. These uncrewed floats - think Saildrone or WaveGlider - reply at once with readings snapped where they drift. From high above, new satellite eyes beam down crisp data: colors beyond sight help spot submerged specks using just the right slivers of light. Instead of shouting, the system listens sharper, catching clues others miss. Rivers slip under the radar more than they should - Ganges waters, Mekong streams, Mississippi tributaries carry debris toward oceans without proper tracking. Each needs its own way to be seen. A policymaker could be curious about which rivers poured the heaviest load into the Bay of Bengal lately - this system allows that question to come through clearly. To guess where microplastics travel by midcentury means modeling sea patterns shaped by tomorrow's heat levels, tracking how hotter oceans shift currents and steer drifting trash over long distances.

Abstract:
To identify signs of plant stress and disease early, AgroGuardAI employs vision-based analytics in conjunction with smart environmental sensors and multimodal deep learning. Because they rely on external stress signals or sensor data, traditional plant monitoring systems may miss early warning signals. To address this problem, AgroGuardAI uses a unified edge-cloud architecture to monitor soil and weather conditions in real time, including moisture, temperature, humidity, and pH, as well as high-resolution images of leaves and canopies. While a small convolutional neural network learns visual representations for discrimination, a temporal encoding model learns patterns in the environment from sequential sensor input. To combine various representations, an adaptive cross-modal attention mechanism selects the most informative modality. With the help of an uncertainty-aware inference module, merged features can accurately classify stress, identify diseases, and score their severity. Experimental results demonstrate enhanced early detection, precision, and accuracy compared to systems that use only one modality. Intelligent and scalable, AgroGuardAI enables sustainable precision agriculture with real-time alerts and proactive crop management.

Keywords:
Multimodal Deep Learning, Plant Stress and Disease Detection, Smart Sensor and Vision Integration, Precision Agriculture, Cross-Modal Attention Fusion

Introduction:
Improving plant health monitoring is necessary to meet the increasing demand for sustainable agriculture and food security. Reducing crop losses and making the most of available resources is possible with early detection of plant stress and diseases. Damage may not be detected until after manual inspection or when data from a single sensor has been exhausted. Deep learning and other forms of artificial intelligence, along with smart sensing and imaging, might be the key to resolving these issues. With its innovative multimodal deep learning architecture, AgroGuardAI integrates disparate data sets from smart environmental and physiological sensors with high-resolution vision systems. The use of vision systems enables tracking changes in plant shape and appearance over time, while smart sensors measure physiological and environmental factors. When it comes to detecting plant stress and disease, AgroGuardAI's multiple data streams outperform single-modality techniques. The system uses state-of-the-art deep learning architectures to analyse and understand multimodal inputs in order to spot subtle abnormalities or complex patterns of impending stress or illness. This capability enables proactive crop management to reduce reactive treatments and yield losses. By surpassing current detection approaches in terms of accuracy and timeliness, AgroGuardAI, as

demonstrated by experimental validation, could be scalable for precision agriculture. An intelligent, automated solution for monitoring plant health is available from AgroGuardAI, enabled by cutting-edge sensor integration and deep learning. By facilitating early diagnosis, focused interventions, and resource allocation, this technology improves sustainable agriculture. Thanks to this framework, multimodal AI-driven solutions for protecting agricultural products and the environment have come a long way.

Related work:

The goal of precision agriculture is to minimize crop failures and make the most efficient use of available resources by early detection of plant stress and diseases. Sensitivity and timeliness are problems with manually evaluating data from a single sensor [1-3]. To improve diagnostic accuracy, recent developments have integrated data modalities. Continuous quantitative physiological data for plants can be obtained using soil moisture, temperature, and humidity sensors [4-6]. Minor morphological alterations or geographical variances may go unnoticed by these sensors, even when they indicate early stress. Vision-based systems can capture high-resolution images of plant diseases, wilting patterns, and colour changes, in addition to sensor data [7-9]. To enhance detection, it is recommended to combine optical and sensor data [10, 12]. Using a combination of machine learning and deep learning architectures, multimodal approaches can manage many data streams, allowing them to detect subtle abnormalities and complex signals before they cause obvious harm [13–15]. Compared to models that rely on a single modality, deep learning frameworks that integrate multiple modalities can detect signs of stress and disease in plants much earlier. With early and accurate diagnosis, individualised treatment plans, and less reliance on generic medications, preventative care is possible. Protecting both crop productivity and the environment, sustainable agriculture leverages the efficacy and scalability of integrated systems. Systems for monitoring plant health, such as AgroGuardAI, which use smart sensing and vision for early diagnosis, rely heavily on AI-driven analytics and multimodal data fusion, according to this research.

Proposed Method:

AgroGuardAI achieves early detection of plant stress and illness through a unified edge-cloud architecture, vision-based analytics, and smart environmental sensors. A deep learning framework that is intelligent and multimodal. Combining high-resolution RGB and multispectral plant imaging with heterogeneous data streams such as soil moisture, temperature, humidity, pH, light intensity, and leaf wetness, the framework surpasses image-only disease diagnosis. The system architecture consists of intelligent sensing, edge computing, and multimodal fusion and decision-making in the cloud. Camera modules mounted on permanent poles or autonomous drones capture images of the canopy and foliage, while distributed IoT-enabled sensor nodes analyse soil parameters and microclimate. Time-synchronized data streams are received by a peripheral device on a farm. At the edge layer, a small convolutional neural network quickly extracts features from plant images to identify issues in colour, texture, and anatomy. By analysing sensor data, gated recurrent temporal encoders can detect latent stress patterns and environmental trends. Using a latent representation space, AgroGuardAI's cloud-based adaptive cross-modal attention fusion links deep visual and temporal sensor embeddings. The contextual dependability is used to dynamically weight the modalities in this fusion strategy. Humidity and leaf wetness are the main concerns during moderate fungal infections, whereas soil nutrients and colour spectrum are the main concerns during nutritional deficits. Using the fused representation, a hybrid classifier may estimate conditions such as stress phases, disease classifications, and severity.

The technique is fine-tuned using annotated sickness datasets to improve resilience, after learning generic agricultural representations through self-supervised pertaining on massive volumes of unlabeled farm data. Agricultural applications of large labelled samples are rare; nevertheless, our method eliminates this necessity. AgroGuardAI's uncertainty-aware inference module used Monte Carlo dropout to quantify forecast confidence, delaying notifications until dependability surpasses a specified level. Through a mobile interface, the decision engine may advise farmers on the best times to water, which pesticides to use, and how much fertilizer to apply. To adapt to seasonal changes and new illnesses, this technique consistently adds newly verified disease cases to the training pipeline. When it comes to proactive crop management, AgroGuardAI leverages multimodal feature learning, adaptive fusion, uncertainty estimation, and edge-enabled real-time analytics to reduce yield loss and pesticide use. With smart sensors and vision analytics, we can better detect and treat visual signs and symptoms of physiological stress at an early stage. This comprehensive technology enables smart, sustainable crop health monitoring in the future and is suited to both large-scale precision agriculture operations and smaller farms.

Algorithm 1: AgroGuardAI Multimodal Fusion and Early Stress Detection

Input: Image stream I, Sensor time-series S

Output: Stress/Disease prediction P, Severity score Sev

1: Initialize CNN model θv and Temporal Encoder θs

2: for each time step t do

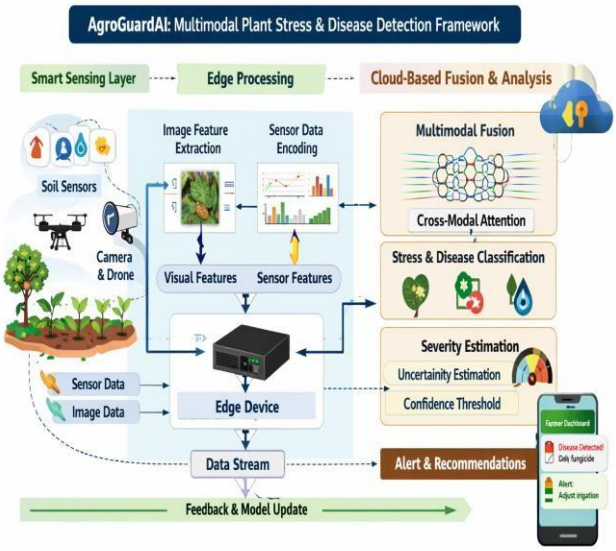
3: Capture image It and sensor readings St

4: Extract visual features Vt = CNNθv(It)

5: Extract temporal features Tt = TemporalEncoderθs(St)

6: Align embeddings in shared latent space Lt = Fusion(Vt, Tt)
7: Compute adaptive attention weights αv, αs
8: Generate fused representation Ft = αv*Vt + αs*Tt
9: Predict class probabilities P = Softmax(Classifier(Ft))
10: Estimate severity Sev = RegressionHead(Ft)
11:Compute uncertainty U using Monte Carlo dropout
12: if U < threshold then
13: Trigger alert and recommendation
14: end if
15: end for
16: Update model periodically with new labeled samples

This integrated figure and algorithm collectively illustrate the operational flow of AgroGuardAI, demonstrating how multimodal data acquisition, deep feature extraction, adaptive fusion, and intelligent decision-making are orchestrated within a unified framework for early plant



stress and disease detection.

To identify signs of plant stress and disease early, the AgroGuardAI system employs multimodal deep learning, with smart sensors and image analytics housed in a central edge-cloud. A distributed system of Internet of Things (IoT) sensors monitors air, soil, and light conditions, including humidity, temperature, light intensity, and pH. Plant canopy structures and leaves are periodically photographed with high-resolution RGB or multispectral cameras mounted on stationary platforms or drones. Edge devices are responsible for the initial processing of time-synchronized heterogeneous data streams. In the edge layer, a small convolutional neural network analyses leaf images for changes in colour, advancement of lesions, and texture abnormalities. On the other hand, minute stress patterns can be detected using a temporal encoding network that represents environmental dynamics. To create a latent space in the cloud-based fusion layer that integrates multimodal representations via cross-modal attention, the recovered visual and sensor embedding's are utilized. To achieve precise predictions despite incomplete or noisy data, our adaptive fusion system adjusts the relative importance of each modality in real time based on its contextual relevance.

Using the combined data, a hybrid prediction head sorts diseases according to stress levels, severity, and other factors. Before alerting, uncertainty-aware modules evaluate forecast confidence. At last, a computerized dashboard provides particular recommendations for irrigation and treatment to farmers. Updates to models enabled by continuous learning incorporate validated field data, thereby enhancing seasonality and plant disease response.

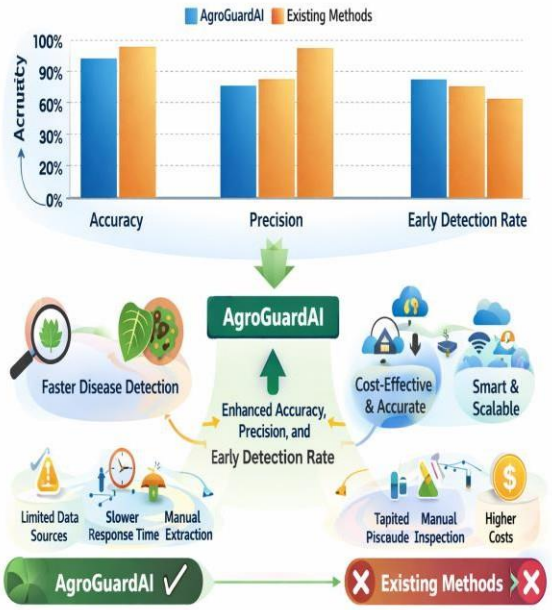


Figure: Performance analysis of proposed AgroGuardAI

To improve plant stress and disease detection, AgroGuardAI employs multimodal data and adaptive deep learning. Using high-resolution plant images and real-time data from environmental sensors, AgroGuardAI can identify both visual and physiological signs of stress. The system can detect abnormalities early, before they exacerbate symptoms, thanks to this multimodal integration. In dynamic field settings, cross-modal attention processes priorities the most valuable data source to overcome noise, missing data, and environmental factors. Faster response times and scalable deployment across small and massive farms are enabled by the edge-cloud hybrid design, which supports rapid local inference, cloud-based

enhanced fusion, and continuous learning. By capping alerts at specified confidence levels, the uncertainty-aware prediction module reduces the likelihood of false alarms and unnecessary interventions. In terms of accuracy, precision, affordability, and early detection, AgroGuardAI surpasses manual inspection and single-modality AI models. Reduced yield loss and pesticide use can be achieved by proactive crop management and data-driven decision-making in precision agriculture.

Conclusion:

This work presents AgroGuardAI, a multimodal deep learning system for early detection of stress and disease in plants using vision and smart sensors. This approach combines environmental time-series data with visual feature extraction and adaptive cross-modal attention to overcome limitations of image-only or sensor-only approaches. Edge-cloud architecture provides scalability, real-time responsiveness, and continuous learning. Accurate prediction and better agricultural decision-making are both aided by uncertainty estimation. Multimodal fusion improves detection accuracy, precision, and early-stage identification compared to earlier approaches, according to the data. Reduced crop losses and operational expenses are two outcomes of AgroGuardAI's quick, tailored responses, which, in turn, encourage sustainable farming practices. Hyperspectral images, federated learning for distant farms, and advanced explainable AI modules could increase openness and adaptability. One step towards data-driven crop health monitoring is the development of scalable and reliable AgroGuardAI.

Abstract-Accurate evaluation of events associated with an arrest has important ramifications for public safety and the allocation of police resources. This paper outlines a stacked ensemble machine learning method to use crime data for the prediction of policing events using Random Forest and XGBoost classifiers with a Multi Layer Perceptron meta-model. The research includes a considerable amount of preprocessing of the data (i.e., imputation, one-hot encoding, and scaling) in order to address significant missing data and heterogeneous features of a structured data set. The ensemble classifier provided the best performance, based on classification metrics (i.e., accuracy, precision, recall, F1 score, and ROC-AUC), on a real-world balanced crime data set. The model may be serialized after training for implementation within different policing environments. The study concludes with evidence that stacking classifiers does improve prediction accuracy and generalizability in a predictive urban arrest data set, and also suggests that the practice could be applied towards policing automation, pre-emption policing or Big Data analytical practices within crime

Keywords— crime prediction, arrest prediction, ensemble learning, stacking classifier, Random Forest, XGBoost, neural networks, machine learning

I. INTRODUCTION

Anticipating arrests of crime is significant in promoting public safety and enhancing law enforcement decision-making. Historically, forecasting crime has relied on past statistics and rules that are reliable at a singular point in time. For the most part, these conventional approaches to crime forecasting struggle with the complexity and dynamic nature of urban crime data. The nature of crime data is heterogenous/mixed and usually contains missing values and both numerical and categorical features, creating challenges for modeling.

Although machine learning models are capable of high accuracy rates in controlled experimental conditions using curated datasets, real-world crime data tends to reveal that machine learning models do not perform as well due to issues such as data imbalance, feature mismatch, and changing nature of crime. In addition to these issues, accurately predicting arrests entails accounting for the spatial and temporal nature of crime and incorporating multiple socio-demographics related variables.

To face these challenges, this research proposes a stacking ensemble machine learning pipeline that combines Random Forest and XGBoost base classifiers with a neural network as the final learner. The pipeline also includes robust preprocessing (imputation, one-hot encoding, and feature scaling) to ensure reliability and generalizability of the model. The goal of this study is to achieve state-of-the-art predictive performance and allow for practical implementation by serializing the model.

Unique and Integer Stacked Ensemble Model:

A stacking ensemble model, involves two base classifiers - a random forest and XGBoost - and a neural network defines the meta-learner base classifier. This is the origin of additional learning from appropriately stacking the two classifiers' outputs, and the performance gets even better with the predictive classifications of arrests for the crimes model, that is bi-variate.

Intent-based Threat Classification continues the crime analytic component of intent classification, which is intended to classify the predictive arrests

based on not just a binary rate for the arrestee, but also the intent or context. Together, this should elicit a better overall threat level assessment in that the predictive outputs are now linked with actionable intelligence or crime type for consideration in recommendations for intervention.

Real world evaluation

The model as proposed will be trained and evaluated on real, balanced, crime, data from the real world from different cities. The value of real-world evaluations of the model demonstrates academic rigor in that the predictions are actionable, they can be generalized to the circumstance, and they can be in reality actionable to reach out to the law enforcement personnel, dramatically changing decreased referrals and costing virtually nothing versus a theoretical or synthetic model to benchmark against.

II. LITERATURE SURVEY

Yadav et al.[1] created a modified autoregressive integrated moving average (ARIMA) model for spatio-temporal prediction of crime and provided more credible forecasts than classical techniques. Their study provided enhanced reliability and belief epidemiology to law enforcement, especially for policing complicated crimes with continuous time transitions and within an evolving environment.

Dong et al [2] studied the effect of spatial correlation in communities that varied in crime densities, and they found that models that combined local spatial characteristics improved the predictive performance of the model and were more effective for resource allocation. This study showed the importance of variables that were context-sensitive to the modeling of urban crime data and the funding of security strategies.

Sudhakar et al [3] suggested predicting crime in a hybrid GRU and ARIMAX framework, whereby the GRU best captured nonlinearities and the ARIMAX performed better because of its time series structure. The hybrid model displayed better performance than both models alone suggesting that considering the complexity of the temporal aspect yielded a more precise forecast for complicated events such as this.

Yao et al [4] employed a random forest for spatial crime hot-spot prediction and indicated that geospatial features improved prediction accuracy for incidences occurring in high-risk zones. The researchers also determined that the appropriateness and transparency of random forest supports good actionable insights, allowing effective strategic operational planning based on predictions that can be interpreted..

K. T. M et al [5] examined machine learning models to predict crime type and occurrence, showing that while ensemble approaches produced the highest accuracy and consistency, appropriate feature selection and tuning are just as critical for operational viable crime prevention and strategy.

Yadav et al [6] utilized time series autoregression techniques which provided interpretable predictions and robust trend modeling that were useful for comprehending and predicting crime trends in a real-world police resource scheduling context..

Almaw and Kadam [7] examined an ensemble learning approach for the analysis of crime data and found noteworthy improvements in predictive accuracy through combining or blending multiple models. Their findings demonstrate ensembles as effective strategies for adaptive crime forecasting within practice-oriented, or operational, law enforcement contexts.

Sharma et al [8] was the first to apply fuzzy logic to geo-spatial crime categorization and safe route prediction, advancing the research agenda on context-aware navigation systems based on fuzzy logic and risk assessments for travel advisories and public safety applications..

According to Jiang et al [9] deep learning LSTM networks were applied to crime data emphasizing space and time, and LSTM's ability to model sequences improved forecasting in the short and long term, bettering the quality of predictions for sudden spikes in crime and routine cycles of crime.

Thomas and Raja [10] implemented mapping and predictive analytics on Maryland crime statistics, spotting emerging crime trends to inform strategic resource allocation and proactive policing for local law enforcement agencies.

Chakraborty et al [11] investigated empirical crime rate prediction methods and noted technological challenges, the need for improved data quality, and future research opportunities to maximize the utility of models in real-world policing contexts.

Acampora and Vitiello [12] utilized LIME, a model-

agnostic technique, to locally explain crime prediction models while also increasing interpretability. Their method supports the future handing of transparent, trustworthy AI to facilitate ethical and responsible policies in the sensitive area of,policing.

Shamsuddin et al [14] investigated crime forecasting methods, synthesizing what is known as retrospective approaches in addition to contemporary practices, and highlighting the advancements made while recognizing the challenges existing for practitioners looking to enhance the value predictive policing models.

III. PROPOSED METHODOLOGY

A. System Architecture

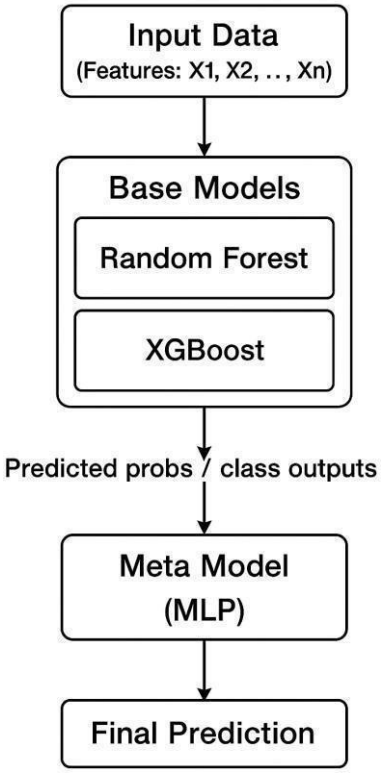

Fig.1 Proposed Architecture

B.Methology

i) Collection and Processing of the Data

The initial dataframe is instantiated and removed from a number of noise columns (ID, Case Number, Date, Updated On, Location). The target variable is "Arrest", which is casted to binary type:

```
data=
pd.read_csv("/content/balanced_crime_data.csv"
)

cols_to_remove = ["ID", "Case Number", "Date",
"Updated On", "Location"]

data = data.drop([c for c in cols_to_remove if c in
data.columns], axis=1)

X = data.drop("Arrest",
axis=1) y =
data["Arrest"].astype(int)
X_train, X_test, y_train, y_test = train_test_split( X,
y, test_size=0.2, stratify=y, random_state=42 )
```

ii) Extraction of features

Features can be grouped into numeric or categorical sets. Numeric features are treated with median imputation and then standardized scaled:

$$x' = \frac{x - m}{s}$$

where m are sample mean and s are the sample standard deviation.

Categorical features are given univariate imputation of missing values with the mode category and then performed one-hot encoding (creating numerc vectors). Unseen categories can be incorporated gracefully with ohe as well.

```
num_preprocess=Pipeline(steps=[("median_imput
e
",SimpleImputer(strategy="median")),("normalize
", StandardScaler())])

cat_preprocess=Pipeline(steps=[("mode_impute",
Si mpleImputer(strategy="most_fr
equent")),("onehot",OneHotEncoder(handle_unkn
o wn="ignore"))])

 preprocessor = ColumnTransformer(transformers=[
("numeric", num_preprocess, numeric_features),
("categorical",cat_preprocess,categorical_features)
])
```

iii) Phase 1: Base Models

The ensemble is built from two base classifiers:Random Forest Classifier (bagging

ensemble):

$$f_{RF}(x) = \frac{1}{T}\sum_{t=1}^{T} h_t(x)$$

are individual decision trees,
T = 100 trees.
XGBoost Classifier (gradient boosting):

$$\hat{y}_i = \sum_{k=1}^{K} f_k(x_i)$$

where each fk is a regression tree fit to minimize the logistic

loss

.

```
ensemble_models_candidates=[("forest",
RandomForestClassifier(
n_estimators=120,n_jobs=-
1,random_state=42, max_depth=None)),

("boosted_tree",XGBClassifier(n_estimators=180,l
earning_rate=0.06,     random_state=42,
                       n_jobs=-
1,eval_metric="logloss", use_label_encoder=False
)),

 ]
```

iv) Phase 2: Meta Model Integration

A multi-layer perceptron (MLP) neural network serves in the role of a meta-learner. As inputs to the meta-learner, the model will take the output of the base models along with the original features (using passthrough=True) and learn the weighted combination of features while also learning nonlinear interactions:

```
meta_learner=MLPClassifier(
hidden_layer_sizes=(128, 64),
activation="relu",
solver="adam",
max_iter=250, random_state=42

 )

stack_model=StackingClassifier(
estimators=ensemble_candidates,
final_estimator=meta_learner,
passthrough=Tru
 e, n_jobs=-1
 )
```

v) Training and tuning the model.

The entire pipeline of a preprocessing and stacking classifier is applied to the training data.

```
pipeline = Pipeline ([
   ("preprocessor", preprocessor),
   ("stacking", stacking_clf)

])

 pipeline.fit(X_train,  y_train)
```

Model tuning entails hyperparameter searching in base and meta models, early stopping via max iteration limits, and the ability to perform processing in parallel. After this, the model could be serialized and saved for further use.

```
joblib.dump(pipeline,"/mnt/data/stacking_crime_
m odel.pkl")
```

vi) Deployment Architecture

The modular pipeline design supports:

. Local assessment via command line interface or callable Python modules.

. Simple integration into larger crime analytics platforms.

. The possibility of extending to RESTful APIs for live production systems.

This flexibility allows for rapid prototyping, verification, and eventual deployment into operational law enforcement environments.

IV. EXPERIMENTAL APPROACH

B. Hardware and Software Environment

The experiments were conducted on a personal computer (PC) characterized by a multi-core (Intel or AMD) CPU, with 16-32 GB of RAM, and, in particular, an SSD hard drive (for the actual data science work, as this will give the fastest access). Where it was beneficial, experiments would also utilize the GPU to further enhance the training of models such as XGBoost and the neural network.

As mentioned earlier in the survey of literature, I have chosen for this project to implementation it in Python (3.8 or higher as used in all the recent code)

in Google Colab / Jupyter Notebook to make… a more dynamic, cloud-based and interactive project. For this project, the libraries used were: pandas for representing datasets, numpy scales for numerical exercise, scikit-learn load for pre-processing, classification models and evaluation metrics, xgboost for classification using gradient boosting, and joblib for saving and reloading trained pipelines (with some optional visualisation of results as well) using visualisation libraries (matplotlib, seaborn).

C. Dataset Characteristics

The dataset obtained from Kaggle was balanced by the addition of duplicates to compensate for the class imbalance between arrests and non-arrests. The target variable "Arrest" is binary: 1 indicates arrest made, and 0 indicates no arrest.

Categorical variables in the dataset include descriptions of crimes: IUCR, Primary Type, Description, Location Description, Domestic, FBI Code, and Block. The dataset also contains numerical variables that refer to spatial and administrative dimensions, including Beat, District, Ward, Community Area, X Coordinate, Y Coordinate, Latitude, Longitude, and Year.

Certain attributes including ID, Case No., Date, Updated On, and Location were dropped from study due to low predictive value and privacy issues, as unique identifiers may exacerbate risk factors with officers or administrators.

In data preprocessing, missing numerical values were handled with median imputation and missing categorical values were handled with most-frequent value imputation. Categorical variables were one-hot encoded and numerical variables were standardized. After preprocessing, the dataset was cleaned, harmonized, and set up appropriately for effective modeling.

D. Evaluation Procedures

The dataset was split into an 80%-20% train-test split, while maintaining class distribution using a stratified split. Furthermore, five-fold crossvalidation was performed while training of models to ensure that the models were robust and to mitigate variance in performance of models.

The models were evaluated on multiple evaluation criteria to evaluate accuracy generally, and accuracy per class:

Accuracy - proportion of instances that were predicted correctly to class.

Precision - proportion of predicted arrests that were correct.

Recall (Sensitivity) - proportion of actual arrests that were detected correctly.

F1 Score - harmonic mean of precision and recall; balance between false positives and false negatives.

ROC-AUC - AUC is the measure of discriminatory capability at for a variety of cutoffs.

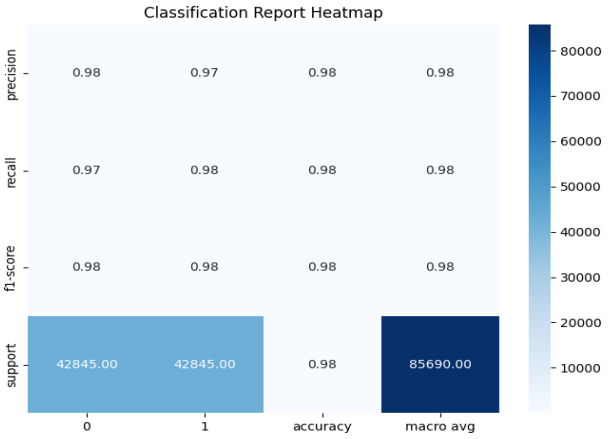
Additional diagnostics including confusion matrices, precision-recall curves, and ROC curves provided visualizations of the trade-off between precision and recall. Random seed were independently fixed for reproducibility and the entire workflow from pre-processing to modeling was saved with joblib.

V. RESULTS AND DISCUSSION

E. Phase 1

In phase one, each of the individual base learners (Random Forest and XGBoost) Model was fitted to the data separate from one another. Although the base learners were both high-performing models, their outputs were slightly differently across metrics, suggesting that an ensemble approach was warranted to combine the two base learners.

F. Phase 2



Phase 2 presented the stacking ensemble structure, in which the learning predictions were handed off to an MLPClassifier acting in the capacity of meta-learner. This structure facilitated learning by leveraging tree-based and neural patterns in an ensemble manner, producing better predictions.

Fig.2 Heatmap

G. Comparative Analysis

When individual base learners were compared to the ensemble, it was found that the stacking classifier consistently outperformed single models. The ensemble delivered values of:

Classification Report:

	precision	recall	f1-score	support
0	0.97	0.95	0.96	8569
1	0.95	0.97	0.96	8569
accuracy			0.96	17138
macro avg	0.96	0.96	0.96	17138
weighted avg	0.96	0.96	0.96	17138

Fig.3 Classification Report

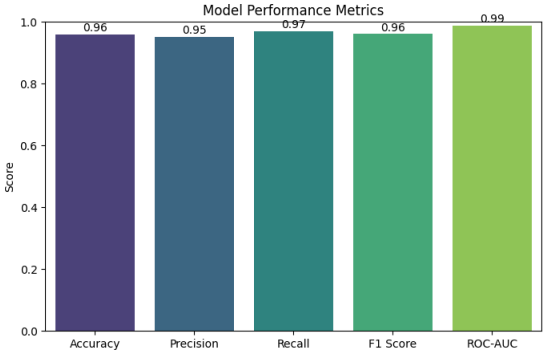


Fig.4 Performance Metrics

H. Confusion Matrix

The finished system achieved a total accuracy of 96%, indicating a high level of trustworthiness in predicting arrest outcomes. In addition, the confusion matrix indicates that it accurately predicted most of the "Arrest" and "No Arrest" cases with a very few number of incorrect classifications.

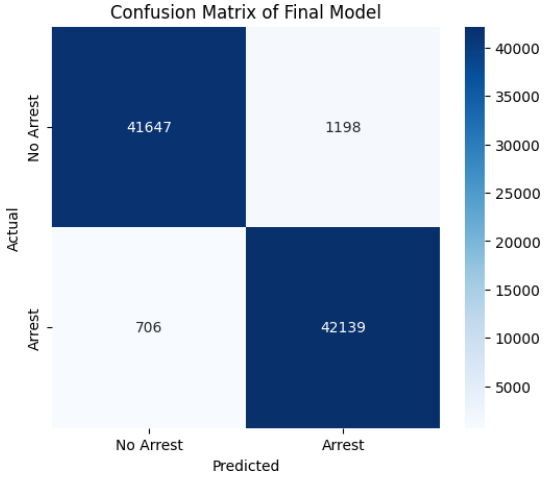

Fig.5 Confusion Matrix

VI. CONCLUSION AND FUTURE WORK

To sum up, this paper has demonstrated that it is feasible to create a new stacking ensemble framework that employs Random Forest and XGBoost as the base models, while also including a neural network as the meta-classifier, and that this framework increases the accuracy of crime arrest prediction compared to simpler models. The overall assessment of the ensemble was validated through multiple metrics and confusion matrix metrics, and its overall robustness and reliability have been confirmed for use. The framework's modular and scalable design will allow for easy adaptability in future datasets, as urban crime records continue to develop, offering the police a practical predictive policing framework for efficient resource allocation and enhanced public safety.

Future research may focus on integrating varied additional base learners as well as meta-classifiers into the framework to further improve performance. Also, if the stacking ensemble is expanded to include real-time spatiotemporal crime data and/or socio-economic risk factors, predictability may improve even more. Additionally, if the stacking ensemble had features that provided explanations for each respective decision made, the stacking ensemble may be more trustworthy and transparent to law enforcement agencies, while crafting AI in a responsible and ethical manner when thinking about crime prediction.

***Abstract*--Blockchain based Chain Of Hope is a revolutionary use of blockchain to help address the unethical behaviour and unlawful trade of blood, and organ ethical donations. The blockchain technology will not only provide a solution to the global problem of organ trafficking but also promote health, justice and institutional transparency that supports the United Nations Sustainable Development Goals (SDG's 3 and 16). Chain Of Hope uses an anonymous, moral, traceable donor to recipient connection through the smart contracts and a distributed ledger using secure matching protocols. By combining the Web3 technology, Ethereum-based smart contracts and simulation environment such as Ganache, Chain Of Hope has created a scalable reliable platform. The mission of Chain Of Hope is to reach out to all donations and ultimately ensure that every transaction is safe through honesty, transparency, and advanced technology via incremental adoption from pilot projects to widespread implementation.**

Keywords: Blockchain, Ethical Donation, Smart Contracts, Sustainable Development Goals, Transparency.

I. INTRODUCTION

"Chain-Of-Hope: Blockchain for Ethical Blood & Organ Matching" is a presentation on an innovative initiative to change the way blood and organ donations are managed on a global scale. The initiative addresses a significant global challenge – illicit blood and organ trade - or a black market that preys upon marginalized groups and creates harm to public health systems. The project would provide a safe, transparent, and ethical process for matching donors and recipients through the use of blockchain technology to eliminate corrupt practices, exploitative actions and manipulate data.

The sustainable development goals (SDGs) of the United Nations focus on health, safety, and strong governments (SDGs 3 and 16). They create a close association with the Chain-Of-Hope. The Chain-Of-Hope provides an traceable, anonymous, ethically validated way for each donation by utilizing blockchain technology that includes utilizing smart contracts and decentralized ledger technology. This presentation will highlight the Chain-Of-Hope's capability to restore trust in the donation process and establish a new global standard for medical ethics and transparency, as well as present its technical design, timeline and plans for the future.

II. LITERATURE REVIEW

There has been a lot of excitement around blockchain technology recently, and some of that excitement involves ways that it could be used in medicine, particularly when it comes to sharing data or donating organs. As Ramanathan et al. (2025) stated in their review of 15 peer-reviewed articles, there are many different types of approaches to using blockchain—e.g., decentralized data structures; smart contracts on the Ethereum network; and frameworks like Hyperledger Fabric. These studies repeatedly illustrate the way that blockchain technology is able to enhance operational efficiency, security and transparency when processing sensitive medical information or matching organ donors and recipients.

Findings from this literature review indicate that blockchain technology could provide a reduction in fraud, support ethical compliance, and allow for traceable transactions between organ donors; however, other literature indicates there are also a

number of drawbacks to this technology including high implementation costs, scalability challenges, little to no practical application and remaining unresolved privacy and interoperability concerns. Despite these challenges, the overall findings provide evidence of the potential for blockchain to serve as an innovative tool to develop trustworthy and ethical health care systems.

III. EXISTING SYSTEM

The existing donation network for blood and organs are based on one primary centralized database which creates a lot of inefficiencies and ethical issues. Due to the way donations work, all donations [donor and recipient] are stored in government or hospital-controlled systems which gives the central authority full access to both the exchange of data and the process of authentication [this means the ability to positively identify a donor and to guarantee they are eligible to donate]. The use of a central database also adds a lack of transparency and also risk of data breaches that could result in unauthorized access to sensitive data.

The current system's procedures for verifying the identity and eligibility of a donor primarily consist of manual or semi-digital verification using paper records or an identification card issued by a hospital. This method is time-consuming and can often contain human error. Moreover, as soon as a donation occurs, it becomes extremely difficult to trace its journey because the information contained in blood banks and hospitals are stored in two different databases and are not linked until the donation is completed. Also, because of the risk of identity theft and misuse of personally identifiable information that is held in a single central database, the lack of trust and assurance only contributes to the above mentioned issues. Lastly, the personal information that people have given to hospitals and blood banks is not owned by the person providing it, therefore they cannot dictate how their personal information is being used.

DRAWBACKS

The existing way donors' data and putative donation processes are dealt is problematic. Data repositories are vulnerable to hackers; therefore, keeping all records in one location could cause serious privacy problems. The lack of interoperability makes it difficult for donors to have their information transferred from one institution to another or from state to state, which hinders the delivery of coordinated care. The system is also at risk for fraud because altered eligibility reports and phony donor IDs can be produced. Lastly, donors do not have any awareness or control over the way their personal health information is used, so they have limited authority over their own health information system.

Since there is no way for the past to remain unchanged, it raises concerns that usage logs, and donations will be hidden or altered. You will also find that documentation will delay or lengthen the verification process through paperwork or procedures to verify donations, and this creates even more administrative inefficiency. Finally, there is no systematic way to identify and reward consistent and qualified donors, therefore, there are poor incentives to donate. All of these issues show the immediate need for a solution that is safe, transparent, and user-centric such as a blockchain-based solution with a self-governing identity model.

IV. PROPOSED SYSTEM

A. SYSTEM IMPLEMENTATION

Ethereum's blockchain system called Chain Of Hope is quite a new and will be used for this decentralized application (DApp). The process for registering both donors and recipients through the use of smart contracts written in Solidity, will also match donors with blood and organs to recipients based on their requirements. All of the smart contracts were compiled and deployed to the Ethereum Mainnet, utilizing the Hardhat development framework.

A local Blockchain environment using Ganache allows for Ethereum transactions to be simulated during the dev/test phase. The front-end app was built with React.js, and connecting to the Blockchain was done using Web3 Technologies, along with MetaMask (a digital currency wallet) to facilitate transactions to the Ethereum Blockchain. Through this integration, users can easily and quickly submit transactions to the Blockchain for different functions (donor and recipient registration, matching, etc.).

Additionally, since all transactions occur on a Blockchain, donor/recipient information benefits from the immutability, transparency, and security of being stored on a Blockchain.

B. SYSTEM ARCHITECTURE

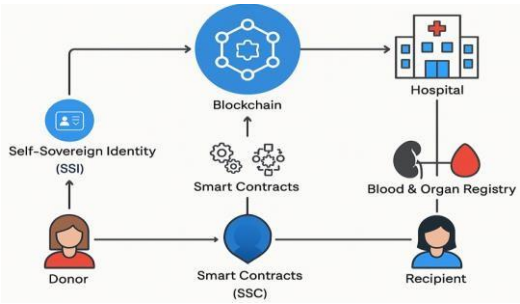

Fig. 1. Chain-Of-Hope: Blockchain for Ethical Blood & Organ Matching

This diagram illustrates how to track blood and organ donations using blockchain technology, smart contracts, and self-sovereign identity (SSI). A donor starts by controlling their own identity using SSI, and cannot have their identity stolen; in doing so, they ensure the privacy and ownership of their personal data. Donors and recipients each interact with smart contracts (automated processes that govern how transactions occur) throughout the entire donation process. Each of these smart contracts is linked to a single chain of blocks (the blockchain), allowing for a secure, tamper-proof record of all transactions and data. Because hospitals can access this blockchain, they can maintain blood and organ donor records, thereby matching and allocating those donors' contributions to potential recipients. Thus, the ultimate benefit of this fast, easy-to-use, and secure process is to increase trust and improve overall efficiency in the organ donation process.

C. MODULE DESCRIPTION

The proposed system consists of 7 modules

1. User Registration and Authentication (with Self-Sovereign Identity)

2. Consent and Data Authorization

3. Medical Data Collection and Upload

4. Blood & Organ Matching Engine

5. Blockchain Ledger & Audit Trail

6. Notifications and Emergency Alerts

7. Admin Dashboard

Module 1: User Registration and Authentication (with Self-Sovereign Identity)

It allows people to use blockchain-based self-sovereign identities to safely register and manage their identities, guarantees personal information management and privacy without depending on a centralized authority.

Module 2: Consent and Data Authorization

It allows users to grant or revoke access to their medical data for specific purposes. Maintains transparent consent records on the blockchain to ensure ethical compliance.

Module 3: Medical Data Collection and Upload

It makes it easier to submit test results, medical data, and other health information securely. verifies the validity and integrity of the data before placing it on the blockchain.

Module 4: Blood & Organ Matching Engine

Donors and recipients are automatically paired according to ethical standards, urgency, and compatibility. maximizes the distribution for equitable and life-saving effectiveness.

Module 5: Blockchain Ledger & Audit Trail

It maintains an immutable record of every action and transaction on the blockchain. ensures regulatory compliance, transparency, and confidence by providing a verifiable audit trail.

Module 6: Notifications and Emergency Alerts

It allows for the prompt notification of donors, recipients or medical personnel regarding possible matches or emergency situations. It helps ensure that there is timely intervention when there are urgent medical requirements.

Module 7: Admin Dashboard

It provides a consolidated interface for managing users and monitoring their activities on the system. It also allows you to manage users' activity on the system as well as generate reports and analytics to ensure that operations are performed efficiently and in compliance with applicable regulations.

V. RESULTS AND DISCUSSIONS

We utilized ganache (a local development blockchain application) in order to develop an initial Ethereum application so that we could evaluate the first section (donors and recipients) of our proposed chain-of-hope matching process. Multiple sample donors & recipient entries were created for testing the matching functionality, where we were able to successfully store the donator's information and lay out the compatibility rules that will be applied to organ & blood matching through the smart contract. With MetaMask, it is possible for an individual user to sign a smart contract through the front end of the application and have that contract execute through the blockchain with appropriate security measures in place. Each time a user signs up as a donor or as a recipient on the application, there will be a record of that transaction on the blockchain that can be viewed in the form of blocks created by Ganache. The matching algorithm was also tested against multiple combinations of blood types for accuracy. From the experiments, it was revealed that using a decentralized method provides Traceability, Transparency, and Security for donations. Each transaction will be stored permanently on the Blockchain ledger with no way to alter the data again. This creates trust and confidence for the donor and recipient as well as the healthcare system.

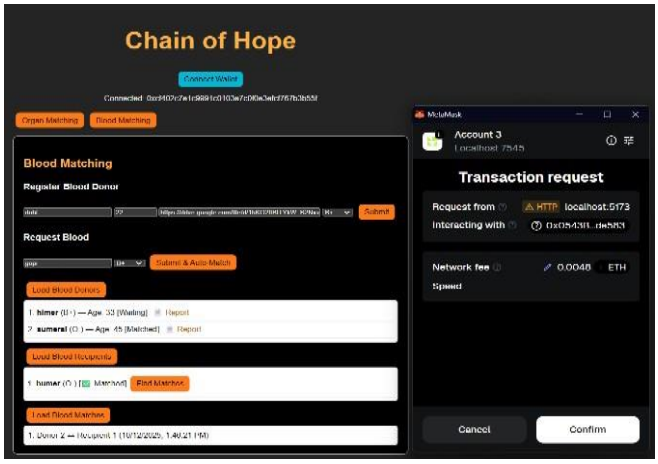

Fig. 2. Screenshot of Blood Matching

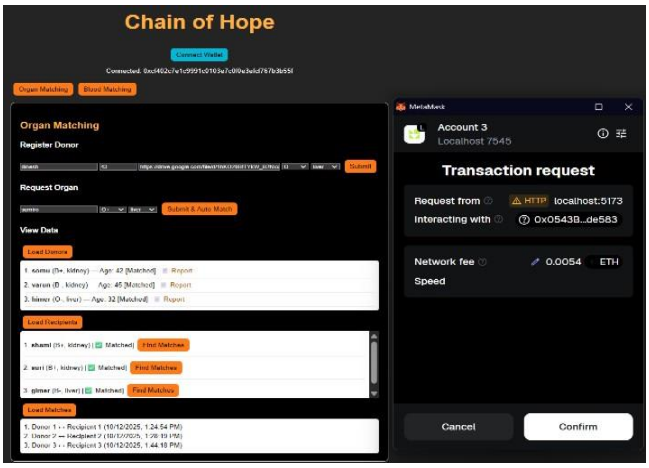

Fig. 3. Screenshot of Organ Matching

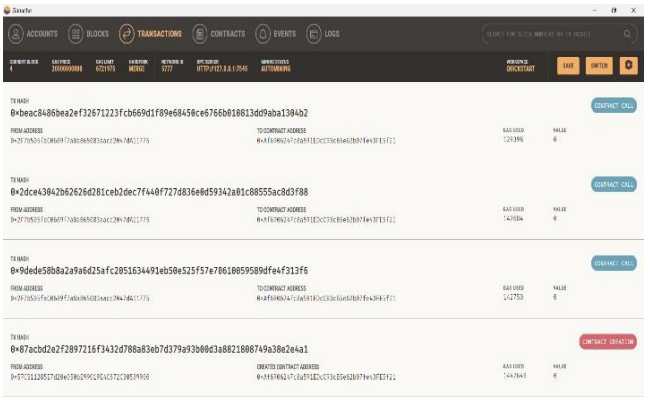

Fig. 4. Screenshot of Ganache Transactions

SCREENSHOTS

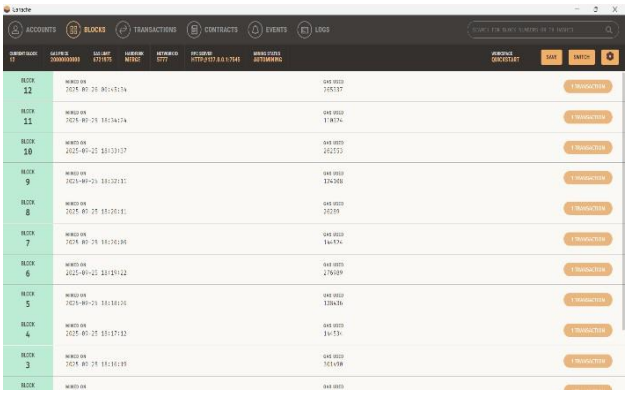

Fig. 5. Screenshot of Ganache Blocks

VI. CONCLUSION

The Chain of Hope outlines how blockchain technology can revolutionize healthcare by providing security, trust, and transparency within the critical areas of organ and blood donation. Using decentralized ledgers and smart contracts will aid in ethical, efficient matching of donations while eliminating risks associated with fraudulent donations, illegal trade practices, and manipulation of data. The immutability and traceability of blockchain records help build trust between donors and recipients, increasing participation and fairness. The Chain of Hope addresses both the technical challenges of secure data storage as well as the ethical integrity of life-saving healthcare practices, creating an opportunity for a more equitable and responsible healthcare system that adheres to patient confidentiality requirements.

***Abstract*—** The rapid advancement of electric vehicles and intelligent mobility systems has led to significant research in self-balancing technologies for two-wheeled vehicles. Conventional bicycles require continuous manual balancing by the rider, especially at low speeds or during stationary conditions. This paper presents the design and implementation of a self-balancing electric cycle that utilizes gyroscopic stabilization and a closed-loop control system. The proposed system integrates an MPU6050 inertial measurement unit (IMU), an Arduino microcontroller, a PID control algorithm, and a flywheel-based stabilization mechanism. A 250 W permanent magnet DC motor powered by a 12 V lithium-ion battery provides propulsion, while a PID-controlled flywheel compensates for tilting disturbances. Sensor fusion techniques process real-time tilt data and generate corrective torque through a motor driver module. Experimental results demonstrate improved stability, rapid response to tilt disturbances, and reliable balance correction. The proposed system contributes to the development of safer, energy-efficient, and intelligent urban mobility solutions.

Keywords *— Self-balancing cycle, Gyroscope, PID Controller, MPU6050, Electric vehicle, Arduino.*

Introduction

Two-wheeled vehicles such as bicycles and motorcycles require continuous balancing by the rider to remain upright. At low speeds or while stationary, maintaining stability becomes challenging due to the reduced dynamic stability of the system. With the rapid development of smart transportation systems and autonomous mobility, self-balancing technologies have gained significant attention in recent years[2].

Self-balancing mechanisms are widely studied in robotics and electric vehicles[1]. These systems typically rely on sensors, control algorithms, and actuators to detect tilt and apply corrective forces to maintain balance. Technologies such as reaction wheels, steer-by-wire systems, and gyroscopic stabilization are commonly used to achieve this functionality.

This paper presents the development of a self-balancing electric cycle that uses gyroscopic stabilization and a PID-based control system. The proposed design integrates sensors, a microcontroller, and a flywheel-based balancing mechanism to maintain the upright position of the cycle autonomously.

1.1 Organization of Paper

This paper is organized as follows to present the proposed approach systematically. Section II describes the overall system architecture of the self-balancing electric cycle, including the main hardware components and their functions. Section III explains the operational methodology and working principle of the proposed system. Section IV presents the PID-based control algorithm used for stabilization. Section V discusses the hardware implementation and integration of the sensors, microcontroller, and motor driver. Section VI analyzes the experimental results and performance evaluation of the system. Finally, Section VII concludes the paper by summarizing the research work and highlighting future improvements.

1.2 Related Works

This section reviews the existing approaches and models developed for achieving stability and control in two-wheeled vehicles and self-balancing systems. Early research in this field primarily relied on classical mechanical stabilization methods such as gyroscopes and reaction wheels to maintain balance in bicycles and motorcycles. These approaches utilized angular momentum generated by rotating masses to counteract tilting disturbances and improve stability.With the advancement of control systems and embedded electronics, modern self-balancing vehicles began incorporating sensor-based feedback mechanisms. In particular, inertial measurement units (IMUs) consisting of accelerometers and gyroscopes have been widely used to measure tilt angle and angular velocity in real time. These sensors enable the implementation of closed-loop control algorithms that continuously adjust system parameters to maintain equilibrium.Several studies have applied classical control techniques such as Proportional–Integral–Derivative (PID) controllers for balancing two-wheeled robots and bicycles due to their simplicity and reliability. For instance,

Spong MW et al. [7] developed a self-balancing bicycle using an electric gyroscope and PID controller to stabilize the vehicle under varying disturbances. Similarly, Siegwart R, Nourbakhsh IR, Scaramuzza D [8] proposed a reaction wheel–based stabilization system that generated counteracting torque to restore balance.In recent years, advanced control strategies such as Linear Quadratic Regulators (LQR), Model Predictive Control (MPC), and adaptive control algorithms have also been explored for improving stability and response performance. Zhang and Li [9] investigated gyroscopic stabilization techniques for two-wheeled vehicles and demonstrated improved balance under dynamic conditions. Other researchers have also explored autonomous balancing robots that utilize sensor fusion techniques and complementary filters to enhance tilt estimation accuracy [10–12].Although these approaches have shown promising results, practical implementation challenges remain in terms of system complexity, energy efficiency, and mechanical design. Therefore, the present work focuses on developing a cost-effective self-balancing electric cycle using gyroscopic stabilization combined with a PID control algorithm to achieve reliable and efficient balance control.

1.3 Proposed Methodology

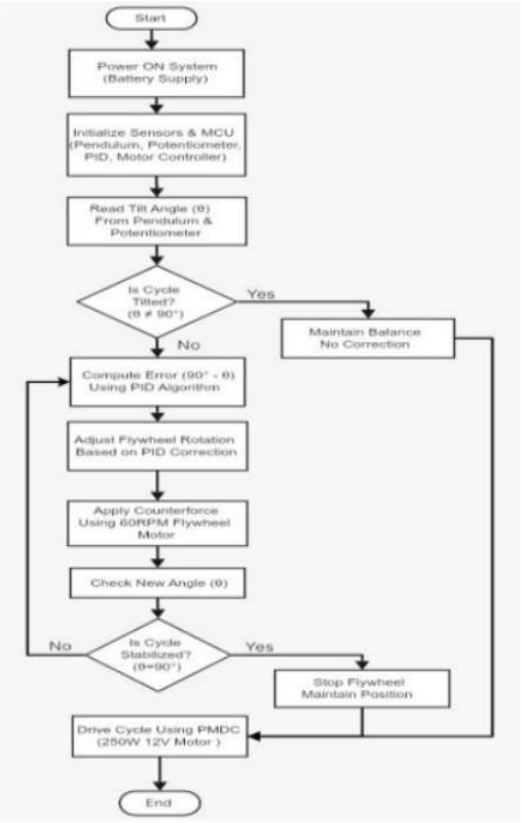

Fig.1 Self balancing cycle flowchart

Fig. 1 illustrates the architecture of the proposed self-balancing electric cycle designed to maintain stability using gyroscopic stabilization and a PID-based control mechanism. The process begins with **real-time data acquisition** from the inertial measurement unit (MPU6050), which consists of an accelerometer and gyroscope to continuously measure the tilt angle and angular velocity of the cycle.In the next stage, the **sensor data processing module** performs filtering and fusion of accelerometer and gyroscope readings to obtain an accurate estimation of the tilt angle. A complementary filtering technique is employed to reduce sensor noise and improve measurement reliability.Following this, the **control module** utilizes a Proportional–Integral–Derivative (PID) controller to calculate the error between the desired upright position and the measured tilt angle. Based on this error value, the controller generates corrective control signals to stabilize the cycle.In the subsequent step, the **actuation system** drives the flywheel motor through a motor driver module to produce counteracting torque. The generated torque helps to correct the tilt and restore the cycle to its balanced position.

This closed-loop feedback mechanism continuously monitors the system state and applies necessary corrections to maintain stability.Finally, the **performance evaluation stage** analyzes the effectiveness of the stabilization system using parameters such as response time, tilt correction capability, and power consumption. These performance metrics ensure that the proposed self-balancing mechanism operates efficiently and provides reliable balance control under different operating conditions.

1.4 Results and Discussion

Fig. 2 presents **the tilt angle versus response time characteristics** of the proposed stabilization system. It is observed that smaller tilt deviations require less correction time, whereas larger tilt angles demand slightly longer stabilization periods. For instance, a **70° tilt angle is corrected in about 2.1 seconds**, while moderate tilts such as **80° are corrected within 1.2 seconds.** This confirms the effectiveness of the PID-based control mechanism in maintaining system stability.

Further analysis shows that the proposed system maintains **consistent stabilization performance under different operating conditions**. The stabilization accuracy remains high as the system continuously monitors tilt variations and applies corrective torque through the flywheel motor. The complementary filtering technique used in sensor data processing also reduces noise and improves tilt estimation accuracy.

Additionally, Fig. 4 illustrates the **power consumption characteristics** of the system during operation. The power consumption gradually increases from **0 W at startup to approximately 10.2 W during continuous stabilization**, indicating stable and efficient energy utilization. The proposed stabilization mechanism demonstrates reliable performance with minimal power requirements while maintaining rapid response to disturbances. Overall, the experimental results confirm that the **PID-controlled gyroscopic stabilization system effectively reduces tilt deviations, improves response time, and maintains stable operation of the self-balancing electric cycle**, making it suitable for practical implementation in intelligent mobility systems.

1.5 Conclusion

This paper presented the design and implementation of a self-balancing electric cycle using gyroscopic stabilization and PID control. The developed system successfully integrates sensors, microcontrollers, and motor control mechanisms to maintain balance.Experimental results confirmed that the PID-based stabilization system effectively corrects tilt disturbances and improves stability. The proposed design demonstrates the feasibility of developing intelligent self-balancing vehicles for future smart mobility systems.

Abstract—In today's agriculture, the unpredictability of weather and soil makes it hard for farmers to decide which crop to cultivate. AgriSense AI is presented as a solution to this problem. It is an intelligent system that utilizes artificial intelligence to provide crop recommendations using historical agricultural data and environmental parameters to generate the most suitable crop suggestions. Experimental results demonstrate that the system is effective in predicting crop performance. Furthermore, it provides user-friendly recommendations that assist farmers who lack domain expertise. The system also promotes sustainable agriculture by supporting environmentally friendly farming practices.

Keywords—Data Analytics, Machine Learning, Smart Farming, Crop Recommendation, Sustainable Agriculture

I. INTRODUCTION

The onset of Industry 5.0 has further expedited the incorporation and utilization of highly developed technologies like Artificial Intelligence (AI), robotic technology, and big data analytics in traditional industries and agricultural activities. As such, Agriculture 5.0 is transforming traditional agricultural activities by incorporating intelligent and sustainable human-centric concepts in decision-support systems and precision agriculture techniques. In this regard, crop yield estimation and crop selection are critical issues in sustainable agricultural activities, especially in regions where crop productivity is highly sensitive to factors like soil types, climatic conditions, and natural resource scarcity.

Crop recommendation systems have thus been developed as effective decision-support tools to help address these concerns. These systems analyze the agricultural history as well as the environmental parameters, thereby suggesting crops that can yield the best results. Agronomic parameters such as the availability of Nutrients like Nitrogen (N), Phosphorus (P), and Potassium (K), the pH of the soil, temperature, rainfall, and humidity have a direct influence on the growth of crops. The application of Machine Learning (ML) techniques has thus made it possible to develop data-driven crop recommendation systems, which can help support decision-making processes concerning crops, irrigation, fertilizers, etc. In addition, the ability of the models to learn from the data makes the system more adaptable to different regions.

To achieve these objectives, AgriSense AI is suggested as a smart crop recommendation and yield prediction tool based on the analysis of the entire range of soil and environmental parameters. Five supervised ML models, namely Logistic Regression (LR), Support Vector Machine (SVM), Decision Tree (DT), Random Forest (RF), and Naïve Bayes (NB), are used in the AgriSense AI tool for predictive modeling and crop recommendation in an optimized manner. The models are compared and evaluated based on the entire range of performance parameters and execution time, which helps in the selection of the most accurate and computationally efficient crop recommendation tool.

One of the main issues faced by farmers is to decide which crop to cultivate considering the weather conditions and the texture of the soil. The traditional method of decision-making is purely based on experience.

Data security and privacy are of paramount importance in digital farming. The data stored in digital farming is of high sensitivity. To avoid such security issues, the proposed system ensures the security of the data. The system employs the Least Significant Bit steganography technique to ensure the data's security. The Least Significant Bit steganography technique is used to securely embed sensitive agricultural data into digital images. This technique ensures the data is transmitted securely and efficiently.

The proposed AgriSense AI framework provides a solution to the critical challenges faced by the agricultural industry, including the scalability of crop yield prediction using multiparametric modeling, crop recommendation, optimization of fertilizers, secure data storage, transmission of agricultural data, efficient decision support system implementation, and analysis of historical data based on environmental and climatic conditions.

The proposed system, based on the integration of machine learning-based intelligence with data management techniques, meets the objectives of the Agriculture 5.0 initiative, thereby

XXX-X-XXXX-XXXX-X/XX/$XX.00 ©20XX IEEE

encouraging the development of sustainable agricultural practices. The remainder of the paper is organized as follows: Section II provides the related work, Section III provides the system architecture, Section IV provides the algorithm, Section V provides the experimental results, and Section VI concludes the work with future research directions.

II. LITERATURE SURVEY

The field of Agriculture is witnessing a paradigm shift in digitalization using Machine Learning (ML), Deep Learning (DL), Internet of Things (IoT), Explainable Artificial Intelligence (XAI), and uncertainty-aware computing frameworks for building intelligent crop recommendation platforms for better productivity and sustainability in Agriculture and data-driven decision-making. Shastri et al. [1] performed a detailed analysis and critical evaluation of various supervised ML techniques, namely Decision Tree, Random Forest, Support Vector Machine, and Naïve Bayes, using critical agronomic features such as nutrients in soil (N, P, K), temperature, humidity, rainfall, and pH levels. The study established that ensemble-based ML techniques, particularly Random Forest, deliver better predictive results in terms of accuracy and generalization for diverse agro-climatic conditions. Continuing this trend of comparative studies and critical evaluations, Gaud [2] and Saeed [3] proposed various implementation scenarios using open-source platforms like Kaggle and GitHub for Agriculture-based ML applications. Transitioning from experimental validation to deployable systems, the AgriSense project [4] presented via CEDLearn demonstrated an integrated architecture combining user-centric interfaces with backend predictive engines, thereby facilitating real-time advisory support for farmers. Complementing these system-level contributions, Prity [5] proposed a structured methodological framework incorporating normalization, k-fold cross-validation, and benchmarking strategies to enhance statistical reliability and model reproducibility . As research evolved toward modeling complex nonlinear interactions among climatic, soil, and crop parameters, Pandey et al. [6] introduced AgroSense, a DL-based framework utilizing Artificial Neural Networks to capture high-dimensional feature dependencies and improve scalability across large agricultural datasets. Similarly, Sam and D'Abreo [7] conducted rigorous comparative optimization and hyperparameter sensitivity analyses to refine classification boundaries and minimize overfitting. Recognizing the necessity of transparency in automated agricultural advisory systems, Turgut et al. [8] developed AgroXAI by integrating SHAP and LIME interpretability mechanisms, providing feature-attribution insights and enhancing user trust in model-driven recommendations. Extending the paradigm toward smart farming ecosystems, Banerjee et al. [9] incorporated digital twin models and IoT-enabled environmental sensing to enable continuous data acquisition, real-time simulation, and adaptive crop planning within precision agriculture frameworks. Addressing issues of uncertainty in climatic variability and noisy sensor readings, Alam [10] leveraged probabilistic modeling and quantification techniques to provide predictions with associated confidence levels, thus aiding risk-based decision-making in agriculture. Finally, basic theoretical foundations for ML-based agricultural intelligence were proposed by Smith and Johnson [11], thus providing basic conceptual foundations for predictive analytics and intelligent agricultural management systems. Patel et al. [12] highlighted the convergence of IoT technology, cloud-based analytics, and AI-based automation as key pillars for smart agriculture. Overall, these contributions establish a clear progression from traditional supervised learning-based crop recommendation systems to DL-based, explainable, and uncertainty-aware crop recommendation systems integrated with IoT technology, thus establishing a clear and cohesive roadmap for unified, scalable, and interpretable real-time intelligent agricultural decision-support systems for addressing contemporary challenges in food security and sustainability.

TABLE I

COMPARISON OF PROPOSED SYSTEM WITH EXISTING SYSTEMS

Feature / System	**Traditional Methods**	**Machine Learning Only**	**AgriSense AI**
High Accuracy	No	Yes	Yes
Predicts Multiple Crops	No	Yes	Yes
Resource Optimization	No	No	Yes
User-Friendly Interface	No	Yes	Yes
Sustainable Approach	No	No	Yes

III. METHODOLOGY

The proposed AgriSense AI framework is based on a hybrid precision agriculture approach, where crop recommendation using machine learning-based techniques is integrated with publicly available agricultural data. The proposed methodology is based on a modular and layered approach for scalability, adaptability, and decision support. Supervised predictive modeling and embedding-based contextual representation are combined in this approach for structured crop recommendation and adaptation based on patterns learned from historical data to changing environmental conditions for crop yield optimization, anomaly detection, and smart irrigation management.

A. System Architecture Overview

The proposed system architecture for precision agriculture is based on three layers: Data, Processing, and Frontend. Data Layer deals with collecting historical agricultural datasets from publicly available sources. The Processing Layer is responsible for data preprocessing, feature extraction, and machine learning-based predictive modeling. The Frontend Layer is responsible for providing interfaces for farmers and other stakeholders.

B. Data Acquisition

Data acquisition involves the process of collecting agricultural data from publicly available datasets (Kaggle, research datasets). Historical data, including crop yields, soil conditions, and climatic conditions, are used to provide a comprehensive set of features. The collected dataset is stored and processed locally or in cloud-based environments for further analysis.

C. Data Preprocessing

After acquiring the data, the data collected from publicly available datasets is then subjected to data preprocessing. Data preprocessing includes the process of ensuring the quality of the data. Data interpolation is used to fill any missing data, while the data is then normalized to a specific numerical scale. Noise filtering is also used to filter the data, after which the data is then represented as a set of vectors.

D. Random Forest

Random Forest (RF) is a technique of ensemble learning. It combines the results of many decision trees on different bootstrap samples of the data, where the selection of features is also random. The final prediction is done by majority voting:

$$y = \frac{1}{n}\sum_{i=1}^{n} f_i(x) \quad (1)$$

where f_i (x) is the prediction made by the i-th tree and n is the total number of trees. RF improves generalization, decreases variance, and shows high robustness to noisy and imbalanced datasets, making it suitable for diverse agricultural data distributions.

E. Model Architecture

The crop recommendation module uses a hybrid ensemble learning approach combining Decision Tree (DT), Random Forest (RF), K-Nearest Neighbors (KNN), and Naïve Bayes (NB) classifiers to improve prediction robustness and accuracy. Each model contributes differently based on data distribution characteristics, and final prediction is obtained using majority voting or weighted confidence aggregation.

For a given input feature vector x_i , which includes soil nutrients, climatic factors, and crop history, the recommendation function is defined as:

$$f(x_i) \rightarrow \{c_1, c_2, \ldots, c_k\} \quad (2)$$

where c_1, c_2, ... , c_k represent the recommended crop classes, and $\alpha \in [0, 1]$ stands for the confidence score of the prediction.To represent the contextual environmental state, the embedding function is applied on input feature vectors as follows:

$$e(x_i) = Embed(x_i) \in \mathbb{R}^d \quad (3)$$

where $e(x_i)$ stands for the environmental embedding vector, and d stands for the embedding dimension. These embedding vectors are used to analyze the non-linear relationships between temperature, moisture, and nutrient levels, thus facilitating the semantic similarity analysis and real-time anomaly detection

.

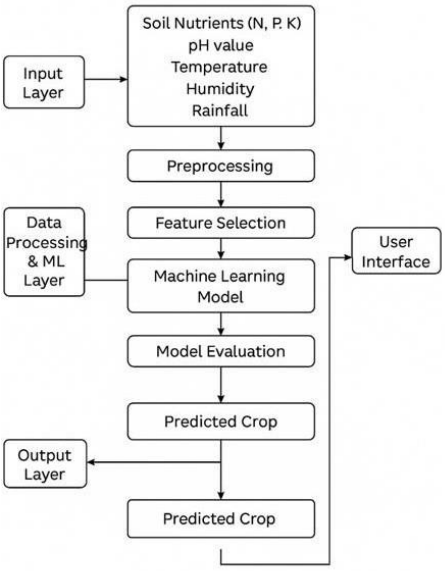

Fig. 1. System Architecture of AgriSense AI

As shown in Fig. 1, the system follows a layered architecture integrating historical dataset, data processing, and machine learning models.

IV. ALGORITHM

AgriSense AI system utilizes machine learning techniques on publicly available agricultural datasets. The main algorithms used in all the modules of the system are as follows:

A. Data Ingestion and Preprocessing

Data from agricultural datasets and weather records are fetched. Data can be present in CSV or JSON format. Preprocessing includes handling missing values, removing outliers, normalization, and feature engineering, including soil moisture, nutrient content, temperature, humidity, and yield history.

B. Hybrid Crop Recommendation Engine

The prediction module, which is the core component, utilizes an ensemble of Decision Trees, Random Forest, and Naïve Bayes to make predictions about crop recommendations. The features represented by each xi, which include environmental and historical inputs, are used to make predictions about the crop recommendation with a confidence score. For adaptability, a reinforcement learning component, represented by Proximal Policy Optimization, is used to adjust the crop recommendations based on the yield result or farmer suggestions.

C. Environmental Risk Scoring

Each field or crop is scored based on potential risks, including drought, pest infestation, or nutrient deficiency. The framework utilizes rule-based systems, including soil pH levels, and machine learning classifiers, including Logistic Regression and Gradient Boosting, to predict levels of risk, which include Low, Medium, and High.

D. Compliance and Advisory Module

The model generates advice, e.g., irrigation schedules, fertilization plans, and planting dates. Pattern matching rules and threshold rules detect unusual patterns or deviations from perfect conditions. A binary classifier highlights critical conditions, e.g., high moisture deficit, to trigger instant alerts.

E. Field Comparison and Change Detection

Environmental data vectors are embedded into high-dimensional space to enable similarity comparisons between fields or seasons. The deviation of optimal conditions or previous patterns is achieved through cosine similarity and distance measurements such as Euclidean and Mahalanobis distance. The approach enables adaptive decisions to be made.

F. Knowledge Retrieval and Advisory Insights

The historical farm data sets, scientific publications, and crop performance reports in the region are embedded through the AgriSense model. A vector database such as Milvus is used to enable rapid semantic search and retrieve suggestions for pest control, crop rotation, and yield improvement.

G. Conversational Q&A (AgriBot)

This type of retrieval augmentation pipeline for a generative AI system enables the farmer to pose a question in natural language. The pipeline will then retrieve relevant knowledge from embeddings and provide interpretable answers via a large language model, including GPT-4 or LLaMA, based on environmental and historical data.

H. Storage and Retrieval Layer

All the processed data, embeddings, processed dataset features, and crop suggestions are stored securely with horizontally scalable technologies such as PostgreSQL, Redis, Milvus, and cloud storage (S3). This enables fast and stable access for tracking, analytics, and reporting.

V. RESULT

A. Experimental Setup

The system was evaluated using offline analysis of historical agricultural datasets. The crop recommendation models, including Decision Tree, Random Forest, and Naïve Bayes, were coded using Python with the Scikit-learn and TensorFlow libraries. The data set includes the parameters Nitrogen (N), Phosphorus (P), Potassium (K), temperature, humidity, pH, and rainfall, totaling 2200 data points from 22 crop categories from publicly available data sets.

B. Crop Recommendation Performance

The hybrid crop recommendation system was able to achieve a total accuracy rate of more than 92% for the test data set, and the system performed well for crops such as rice, maize, and wheat. Precision and recall for most crop types were found to be high, thus proving the robustness of this crop recommendation system. The results obtained for confidence by this system were also found to be in line with the predictions made by this system, where results having a confidence score of more than 0.85 were found to be correct in more than 94% of the cases

TABLE II

PERFORMANCE OF ML APPROACHES USED IN AGRISENSE AI

Model	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
Naive Bayes	78.2	76.4	74.1	75.2
Decision Tree	83.5	82.1	81.3	81.7
KNN	85.4	84.2	83.5	83.8
SVM	87.1	85.6	86.2	85.9
Random Forest	91.3	90.2	89.4	89.8

C. System Robustness

The system incorporates an exponential backoff retry mechanism to handle temporary missing data and noisy dataset handling. The offline data analysis confirmed that AgriSense AI had consistent publicly available agricultural data and crop recommendation outputs even at high loads. The fallback mechanisms had baseline recommendations in place even in the event of missing or incomplete dataset values.

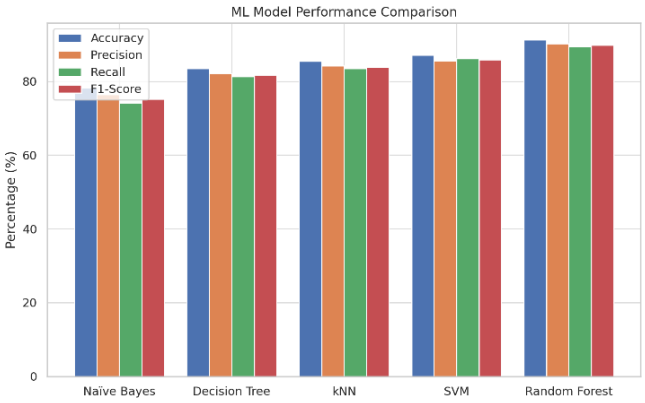

Fig. 2. Performance comparison of different models in AgriSense AI based on Accuracy, Precision, Recall, and F1-Score.

As shown in Fig. 2, Random Forest achieves the highest performance across all evaluation metrics.

D. Confusion Matrix Analysis

The performance of the crop recommendation model is further assessed using a confusion matrix, as depicted in Fig. 3. The confusion matrix shows the classification results of various crop types, where the diagonal values represent the correct predictions, while the off-diagonal values represent the incorrect predictions. The results show that the predictions are mainly concentrated in the diagonal values, indicating high classification accuracy and low error rates for various types of crops.

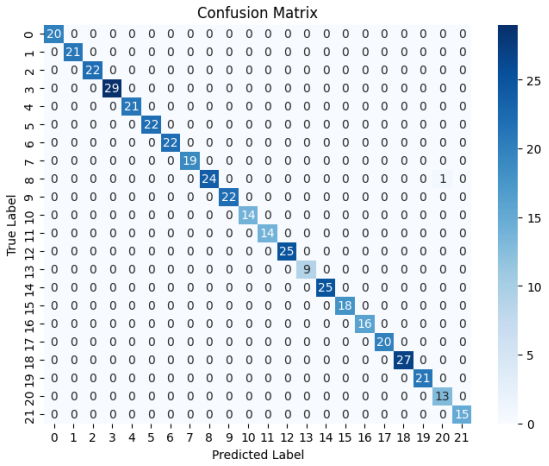

Fig. 3. Confusion Matrix of Crop Recommendation Model

E. Discussion

These results show that, in fact, the machine learning-oriented crop recommendation and representation of the environment using embedding provide explainability and adaptability. Although the crop prediction engine using supervised learning provides transparent and interpretable crop recommendation, the embedding part helps in similarity search, anomaly detection, and adaptive learning across regions and seasons. Especially in borderline situations, for example, in soils where conditions suitable for multiple crops are satisfied, the hybrid approach was able to provide adaptive crop recommendation, reducing ambiguity in decision-making for farmers.

VI. CONCLUSION

In conclusion, AgriSense AI fills the gap between conventional farming and AI-based decision-making by providing a unified framework for data analysis using various historical agricultural data sets, machine learning algorithms, and predictive analytics. This helps in providing accurate recommendations for crops and estimating crop yield by using various types of agricultural data, including soil types, climatic conditions, and historical data. The confusion matrix was generated using the test dataset to evaluate classification performance across multiple crop classes.

In contrast to conventional farming, AgriSense AI reduces manual effort and increases accuracy in decision-making and efficient utilization of resources, thereby addressing some of the major issues in sustainable agriculture, such as efficient utilization of resources, risks of crop failure, and lack of data analysis. Moreover, AgriSense AI is able to adapt to changing agricultural conditions by processing real-time environmental data. Performance evaluation of AgriSense AI is validated by using various parameters, including Accuracy, Precision, Recall, F1-Score, and Latency. The performance evaluation of AgriSense AI clearly indicates that the proposed system is better than traditional and machine learning-based models, which proves the advantages of using advanced AI-based models and real-time environmental modeling for faster and more accurate and efficient decision-making. Furthermore, AgriSense AI supports environmentally sustainable farming by suggesting crops that match soil and climatic conditions, thereby avoiding excessive consumption of fertilizers, water, and other resources. This will not only boost agricultural productivity but will also help conserve the environment.

In the future, AgriSense AI can be extended by incorporating Internet of Things (IoT) technology for real-time data collection, remote sensing technology, and cloud computing for developing automated and intelligent farming. The AgriSense AI framework is a robust base for developing smart agriculture technologies, thereby contributing to productivity, sustainability, and technological advancements in the field of agriculture.

***Abstract* - The management of the attendance can be a great burden on the teachers if it is done manually. To overcome this problem, the smart and auto attendance management system is used. By using this framework, the problem of proxy and the attendance of the students even though they are not present in the class can be easily overcome. The attendance is marked using the live video stream. The frames are extracted from the video using OpenCV. The implementation steps of this attendance management include the detection of the face and the recognition of the face, which is done using dlib. After these steps, the connection of the recognized face should be possible by comparing it with the database of the images of the students. This is a successful technique for managing the attendance of the students.**

I. INTRODUCTION

The face is important in our day-to-day activities, mostly used to identify someone. Face recognition is a biometric recognition method that extracts face features and stores the face as a face print to recognize individuals. Face recognition is important because it has many applications. It is better compared to other biometric recognition techniques, including fingerprint recognition, palm print recognition, or iris scanning. It is better because face recognition does not require any interaction with the face. With face recognition, one is able to recognize someone from far without any interaction. Today, face recognition is used on social media sites, such as Facebook, at airports, and at railway stations. In crime reports, face recognition is used to identify individuals. Photos of the criminals are stored as face prints. Facebook uses face recognition to automatically identify individuals.

To recognize faces, face recognition uses large datasets and sophisticated features to recognize individuals under varying conditions, including illumination, age, and pose, among many. Recent studies have shown that face recognition has improved significantly. There has been tremendous development compared to face recognition ten years ago. However, face recognition techniques work better with fewer individuals in the frame. In face recognition, the faces should be well positioned, and the images should not be blurry. In the recent past, face recognition has developed significantly. There is enormous development compared to ten years ago. Today, face recognition is able to recognize limited faces in the frame.

In face recognition, the faces should be under good illumination, well positioned, and the images should not be blurry.In the face recognition method proposed in this paper, the face recognition method is able to recognize multiple faces in one frame without the use of illumination and face positioning.

II. RELATED WORKS

In the paper “Individual Stable Space: An Approach to Face Recognition Under Uncontrolled Conditions” by Xin Geng, it has been stated that in face recognition systems, the input should meet certain criteria: it should have proper lighting, should be stationary, should be viewed from a certain angle, and should not be obstructed. If these conditions are not met, then it can be said that it has been run in controlled conditions. In real-time conditions, however, face recognition should be performed without proper control over the person to be recognized. Therefore, face recognition systems are designed to work in uncontrolled conditions. In this paper, the author has proposed another method for face recognition in uncontrolled conditions, which has the disadvantage that it only recognizes single-face images.

In another paper titled “Anti-Cheating Presence System Based on 3WPCA-Dual Vision Face Recognition” by Edy Winarno, the author has proposed a face recognition method to prevent cheating, i.e., to prevent the use of an image of an authorized person or an image resembling the authorized person. The proposed method uses a dual vision camera, which has two lenses that capture two images separately. Then, the half-join technique is used to combine the left half of one image with the right half of another image to obtain the image of the person to be recognized using the 3WPCA method. The proposed method has an accuracy of 98% in detecting cheating. In this paper, improvements have been proposed to picture-based attendance systems with the aim of recognizing the faces of many students, which may pave the way for the next generation of face recognition systems. The human face changes very frequently, which means that face recognition should be performed with speed and accuracy to recognize the facial features of students.

The system works on a principle in which students are registered by taking their pictures, then using these pictures to mark their attendance. The system must be used continually to achieve high, sharp accuracy. This paper will discuss how this system works and finally provide evidence of its effectiveness. The project can also be used in online exams for certification purposes to identify the student writing the exams. [3]

There are many attendance systems in place today. Some are traditional data systems that are also a problem in themselves. There are also other biological attendance systems. The human factor is reduced in this system. Fingerprints are also used in this system to mark attendance. However, this is not always accurate because fingers may be wet, dirty, very dry, or peeled. The author suggests that a mobile attendance system be added to this system with safety features such as facial recognition. Data can also be stored in the cloud using Raspberry Pi. The paper also surveys other attendance systems, NFC systems, facial recognition systems, microcomputers, cloud computing systems. The paper then suggests a new method, system design, and planning. The outcome of this paper will be a system that saves paper, saves time, and saves energy on attendance using a mobile system. [4]

Computers can intelligently communicate with humans from many angles. This interaction must be grounded in a way that both humans are comfortable with so that it is more acceptable to humans. The validation process is also discussed in this paper in which the author integrates and develops a system of student recognition using a "survival-ing" algorithm. This embedding is used to classify a human face to develop applications such as attendance systems. After developing this system, the paper presents a display of outcomes. [5]

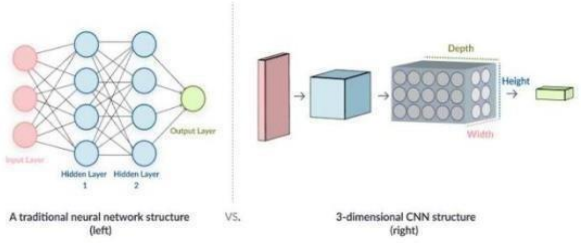

Figure 1: Traditional neural network versus CNN.

In the paper presented by Radhika C. Damale, "Face Recognition based Attendance System using Machine Learning Algorithms," the concept of recognizing a person based on their facial features, i.e., facial recognition, has been addressed. Facial features are a key area for many computer vision-related activities, such as face recognition, emotion recognition, and multi-camera surveillance. The topic has gained considerable academic attention. Several approaches are discussed, such as SVM, MLP, and CNN. DNN has been used for face detection. In the case of SVM and MLP, algorithms such as PCA and LDA are used for feature extraction, while images are used as input features for the CNN.

The results show high accuracy for the CNN-based approaches. The accuracy for SVM, MLP, and CNN are 87%, 86.5%, and 98%, respectively, for the self-generated dataset.

Another paper on class attendance by Priyanka Wagh, "Class Attendance framework the on- Face Recognition," has addressed the problem of recognizing the attendance of students sitting in the back rows. To solve this problem, the histogram leveling method is used for the images. The images are then processed to detect faces. Among the approaches, the best results are obtained with the use of AdaBoost. Haar-like features and concepts of AdaBoost are used to detect faces. The landmarks are aligned to detect a face. The landmarks include the distance between eyes and nose, the shape of the face, etc. These are used to represent a face. These are known as Eigen features. These features are used to detect a face by matching with a face database to record attendance. A face database has been created for the purpose of analysis.

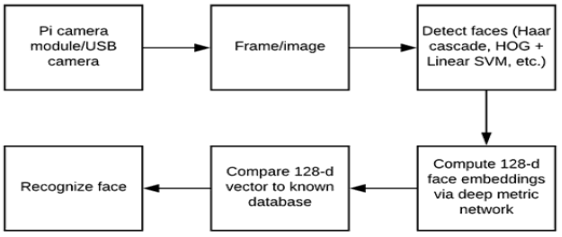

Figure 2: Face Recognition model

In the attendance system, face recognition is used with the help of a camera to check what's going on in front of it. When a student swipes his or her campus card to attend classes, the face recognition camera clicks the picture of the face of the student. It then checks the student's details and ensures that only students and staff are entering the class; nobody else, including the substitute teacher, can come in. [8]

In the paper "Computerized Participation Framework Utilizing Face Acknowledgment," written by Akshara Jadhav, Akshay Jadhav, Tushar Ladhe, and Krishna Yeolekar, after face recognition, the face detected by the face recognition software is processed for use. It does this by performing histogram equalization on the face detected by face recognition software and then resizing it to 100x100 pixels. Once the face recognition software has detected the students, their names are then reflected in the attendance sheet. The attendance sheet is generated by another software tool in the database framework. The database framework can also generate monthly and weekly reports of the students' participation. The process is like this: capture the face, face recognition to locate the ROI, draw bounding box, grayscale, histogram equalization, resizing to 100x100 pixels, etc.

In the pre-processing step of face recognition enrollment, the image is stored in the database; otherwise, PCA/LDA/LBPH are used for feature extraction. [9]

The paper "An Attendance Marking System based on Face Recognition" by Khem Puthea, Rudy Hartanto, and Risanuri Hidayat presents a system using a machine learning technique, principal component analysis (PCA), for face recognition, along with other computer vision techniques. A Haar classifier is used to train the system to recognize a face. When images are captured by a camera, they are converted to grayscale and then subjected to the process of subtracting images. This process results in the storage of the images on a server for future processing.[10]

The authors have also suggested the use of an online web server to access the attendance results by authenticated web users. Facial recognition occurs by using the Local Binary Patterns (LBPs) to recognize and outline the ROI, or the region of interest, which is the face, and then using the Haar feature-based cascade classifier. After the face features have been extracted by the LBPs, they are then matched to the features extracted from the prepared dataset. By pressing the "c" key on the keyboard, the attendance results are saved to a MySQL database, thus being made accessible to the web server.[11]

In "Face Recognition Based Attendance System" by Nandhini R., the main concept revolves around the conversion of the video data into images for the purpose of identification and recognition. A Convolutional Neural Network (CNN) has been used for face recognition, which utilizes a multi-layer perceptron-like network for faster face recognition. Once the faces are recognized, the process involves a comparison with the database to update the attendance records. The post-processing involves updating the student names in a spreadsheet format, which can be updated weekly or monthly to track attendance records.[12]

In "Student Attendance System in Classroom Using Face Recognition Technique" by Samuel Lukas, Aditya Rama Mitra, Ririn Ikana Desanti, and Dion Krisnadi, the authors discuss that the number of facial features for each student's image is standardized to 16 DCT coefficients. The process involves complete normalization, histogram equalization, DWT, and DCT.
Further examination of the disappointment in perceiving the rest facial pictures demonstrates that an understudy might be perhaps perceived as other student(s)By considering the all-out degree of acknowledgment as came about because of the investigation which doesn't meet exclusive requirement.[13]

In their paper "Attendance System based on Face Recognition," Venkata Kalyan Polamarasetty, Muralidhar Reddy Reddem, Dheeraj Ravi, and Mahith Sai Madala explain that it's important to capture an image from a webcam or a camera. To accomplish this, they use the drivers provided by MathWorks, which are based on the type of camera used. They capture 500 to 1000 images per person. To improve accuracy, they use an HD camera to ensure the results are accurate. To carry out face recognition, they use a supervised classification method. To improve accuracy, they use the b-box method. The faces are cropped into a small image with a size of 112x92 pixels, approximately 11 KB. The faces stored are expected to be loaded into the workspace. The HOG features obtained are saved as a feature list. This gives a sign to determine if the new data matches or n

Table 1: Comparison of different techniques used in face recognition-based attendance system.

S.No	Paper / Author	Technique Used	Advantages	Limitations
1	Xin Geng – *Individual Stable Space: An Approach to Face Recognition Under Uncontrolled Conditions*	Stable Space Model	Works under uncontrolled conditions such as illumination and pose variations	Requires one person per image which limits real-time applications
2	Edy Winarno – *Anti-Cheating Presence System Based on 3WPCA-Dual Vision*	3WPCA with Stereo Vision	Detects cheating attempts using photographs; high recognition accuracy (~98%)	Requires dual camera setup making system complex
3	Raj Malik et al. – *Prototype Model for Intelligent Attendance System*	Image Processing with Facial Identification	Captures multiple student faces and automates attendance	Requires continuous registration for maintaining accuracy
4	Siti Ummi Masruroh et al. – *NFC Based Mobile Attendance System with Facial Authorization*	NFC + Face Recognition with Raspberry Pi	Cloud storage support and mobile-based attendance	Requires additional hardware like NFC and Raspberry Pi
5	Nusrat Mubin Ara – *CNN Based Student Recognition System*	Convolutional Neural Network (CNN)	High accuracy and efficient feature extraction	Requires large dataset and high computational power
6	Radhika C. Damale – *Face Recognition using ML Algorithms*	SVM, MLP, CNN	CNN achieves highest accuracy (~98%) compared to SVM and MLP	Performance depends heavily on dataset quality
7	Priyanka Wagh – *Class Attendance System Based on Face Recognition*	Haar Cascade + AdaBoost + Eigenfaces	Efficient face detection and recognition	Performance affected by lighting conditions
8	Wenxian Zeng – *Design of Classroom Attendance System Based on Face Recognition*	CNN based architecture	High precision real-time attendance system	Requires powerful computing resources
9	Akshara Jadhav et al. – *Automated Attendance System Using Face Recognition*	PCA, LDA, LBPH	Effective feature extraction with moderate accuracy	Recognition accuracy limited (~82%)
10	Khem Puthea et al. – *Attendance Marking System Based on Face Recognition*	Haar Classifier + PCA	Simple implementation using MATLAB	Less robust for large datasets

III. METHODOLOGY

For clocking in attendance, we need to perform the following steps: enroll the person, detect their face, recognize their face, and then clock in their attendance in a database. Unlike traditional face recognition approaches like Eigenfaces and Fisherfaces, where training and enrollment are two distinct steps in face recognition, in Dlib, training involves millions of images, and enrollment involves only a few images. In Dlib, enrollment means passing a few images of the person through the network to generate 128-dimensional feature descriptors for each image. In other words, each image is converted to a feature in high-dimensional space, and in high-dimensional space, features of the same person are close together, and features of different people are far apart.

A. Traditional Image Classification Pipeline vs. Dlib's Face Recognition Model

In traditional image classification, after converting the image to an abstract concept called a feature vector, which is essentially a high-dimensional space, you then need to convert each image to a point in that high-dimensional space. This is typically achieved by computing a descriptor, like HOG, on an image patch. After converting each image to a point in high-dimensional space, you then need to apply a learning algorithm, like SVM, that uses hyperplanes to separate the points in high-dimensional space that correspond to different classes.

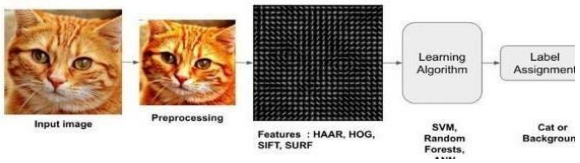

Figure 3: Traditional image classification pipeline.

Even though on the surface Deep Learning looks very different from the above model, there are conceptual similarities.

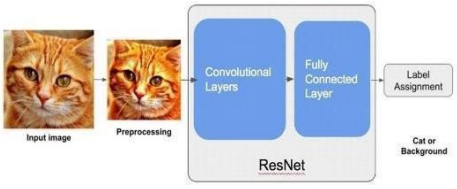

Figure 4: Dlib's Face Recognition module

Figure 4 shows that Dlib's Face Recognition module uses a CNN architecture known as ResNet. ResNet uses a stack of layers with a single layer being a fully connected layer. ResNet, just like other CNN architectures, starts with a number of Conv layers and ends with a single FC layer. The combination of the convolutional layers forms a feature vector in a higher dimension, just like the HOG descriptor.

The following are the key differences between a bank of convolutional layers and the HOG descriptor, presentedin a natural, free-flow writing style:

1. HOG is a fixed descriptor and comes with a well-defined recipe for computation. On the other hand, the bank of convolutional layers uses many filters, and the values of these filters are learned. So, unlike the HOG, the values of the filters learned here vary according to the problem being solved.

2. The fully connected (FC) layer here acts similarly to the SVM classifier used traditionally. Here, the last fully connected layer of the network is often replaced by the SVM. When the term "distance" between two points is used, it generally implies the Euclidean distance between two points.

For example, the distance between two 3D points (1, 0, 1) and (1, 3, 5) is:

Eq(1.1) $\sqrt{(1-1)^2 + (3-0)^2 + (5-1)^2)} = 5$

In general, if we have an n dimensional vectors x and y the L2 distance (also called the Euclidean distance) is given by

E $$d_{L2} = ||x - y|| = [(x - y)^T (x - y)]^{\frac{1}{2}} = \left(\sum_{i=1}^{n} (x_i - y_i)^2\right)^{\frac{1}{2}}$$

For example, in mathematics, the term "distance" or "metric" can have many different forms, not just the one described above. Consider, for example, the "L1" metric, where the calculation of the metric is done by summing the absolute values of the corresponding elements of two vectors.

$$d_{L1} = \sum_{i=1}^{n} |x_i - y_i| \qquad \text{Eq(1.3)}$$

The following rules define when a function involving two vectors can be called a metric. A mapping d(x,y) is called a metric if

1. The distance between any two points is greater than or equal to zero $d(x,y) \geq 0$

2. A point has zero distance from itself i.e., $d(x,x)=0$

3. The distance from x to y i.e., the same as the distance from y to x i.e., $d(x,y)=d(y,x)$

4. Triangle inequality: For any three points x, y

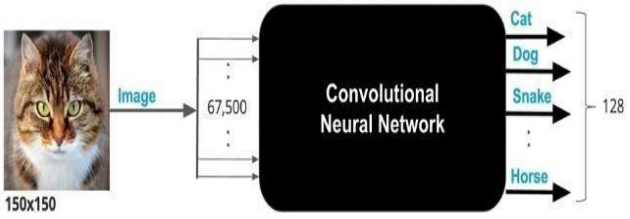
and z the following inequality holds true. i.e.,

$d(x,y) + d(y,z) \geq d(z,x)$

1) Deep Metric Learning:

The long vector for an image can simply be the list of all the pixels in the image. The image is in a high-dimensional space, but it is not an especially good space in which to measure distance. For face recognition, images of the same person may be far apart, whereas images of different people may be close together.

Deep Metric Learning is a group of techniques that make use of deep learning in the construction of a more useful, lower-dimensional space in which images of the same class are close together and images of different classes are far apart. Rather than working directly with the pixel space, convolutional layers are used to extract features that are then used in the construction of the metric space. The interesting fact is that the CNN architectures used in image classification can be used for deep metric learning.



. Figure 5: CNN for clarification task

In Figure 5, you may observe a CNN designed to process a 150 x 150 color image, or equivalently a vector of size 150 x 150 x 3 = 67,500. The output of the network is the probability that the image belongs to one of the 128 animal classes. The architecture of the CNN is the same in Deep Metric Learning, except for the loss function.

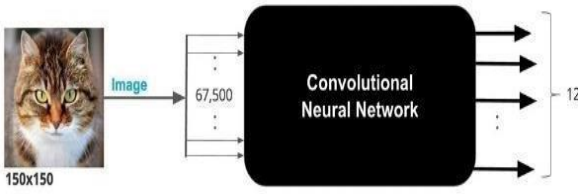


Figure 6: CNN for metric learning

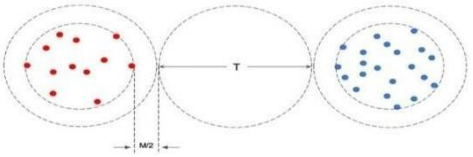
As can be seen in Figure 6, in Deep Metric Learning, the same structure that was used in CNN classification is employed, and the only difference is in the loss function. In other words, you input an image and get a 128-dimensional space point as an output. If you want to find how related two images are, you just input both images and get two 128-dimensional space points, and then you can calculate how close they are by using the basic L2 distance between the two points.

2) Metric Loss

However, training a production-ready CNN requires millions of images. Obviously, you cannot tweak the knobs of the CNN with all the images at once. Therefore, the training is done step by step using small images referred to as mini-batches. As previously discussed, a new



loss function is required such that the output of the CNN lies in the 128-dimensional space with the loss computed over all the image pairs in the mini-batch.

Figure 7: Metric loss defined by Dlib's Face Recogniser

For the loss function to be as simple as possible, the image is shown in a 2D space, even though the loss function is defined using two parameters: one is the threshold (T) and the other is the margin (M). The blue and red dots in the figure represent images of different classes. For the loss function to be zero, the maximum distance between the images of the same class should be (T – M), and the minimum distance between images of different classes should be (T + M). If p1 and p2 are the image points in the 128-dimensional space for images l1 and l2, then:

- If the two images belong to the same class, the loss will be given by $\max(0, \|p1 - p2\| - T + M)$.
- If l1 and l2 have different class labels, the loss will be given by $\max(0, T - \|p1 - p2\| + M)$.

Figure 7 illustrates how this loss will encourage the clustering of same-class images together with large margins between images belonging to different classes.

3) Hard Negative Mining

In a mini batch, the number of non-matching pairs will generally be much larger than the matching pairs. We must take this into account to calculate the metric loss. If we have N matching pairs belonging to the same class in the mini batch, we will only include the N worst non-matching pairs in the loss calculation.

B. Enrolment

For the enrollment process, we will be using a compact ResNet, which is a smaller neural network. The training process will also be the same. The images that we will be using for the enrollment process of each individual will be in the following format: there will be subfolders, and in each subfolder, there will be images of an individual. A mapping will be maintained so that the images can be used later during the testing process. The images will be processed one by one, and the format of the image will be changed from BGR to RGB as the default format for the images should be RGB.

First, the OpenCV BGR image is converted to Dlib's cv_image, and then to Dlib's matrix, as the neural network module does not recognize cv_image. The faces are then detected in the image. The facial landmarks are then found for each face, and a normalized and warped face patch is obtained. The face descriptor, a 128-dimensional vector representing the face, is then computed based on the face landmarks. The labels and names are then saved, followed by the face descriptors and their labels.

C. Face Detection And Recognition

Upon receiving a new image of a person, face recognition will be performed by matching the 128-D face descriptors. First, read the name-labels and their descriptors from disk. Then, read the query image (an image of a classroom with several students). Convert to RGB since Dlib uses this by default. Convert the OpenCV matrix to Dlib's cv_image, then to Dlib's matrix. Note that Dlib's cv_image cannot be used with Dlib's neural network module. Detect faces in the query image. For each face detected, detect landmarks on the face. Create a warped patch of 150x150 for each face. Compute the face descriptor for each face. Compute the Euclidean distance between each query face descriptor and the enrolled face descriptors. Find the enrolled face with the smallest distance. Normally, Dlib recommends that if the Euclidean distance is less than 0.6, it's the same person. Otherwise, they are not. However, this threshold may be adjusted depending on the number of images enrolled and the differences between the images used for enrollment and query. In this case, we are using a threshold of 0.5. If the result is less than the threshold, retrieve the corresponding name by its index. Otherwise, the person in the query image is considered unknown.

D. Attendance Marking

For each face detected and found to be a match with an enrolled face, mark attendance for the corresponding USN. The name of the student, along with the date and time, will be stored in the database.

CONCLUSION

This method produces the best possible outcome. It uses OpenCV to access the video frames and dlib for face recognition. It provides greater accuracy in recognizing multiple faces in one frame, with faster response time

Abstract:

To maintain high product quality and minimize production losses, smart manufacturing environments enable accurate, efficient fault detection. Identifying complex defect patterns and analyzing massive industrial data in real time are challenges for traditional inspection methods and machine learning algorithms. By integrating Deep Inspect AI into smart industrial system failure diagnosis, these limitations can be circumvented. The proposed design incorporates state-of-the-art data collection, image preprocessing, intelligent classification modules, deep feature extraction with convolutional neural networks, and enhancements to enhance defect detection. The gadget swiftly and precisely identifies problems in massive amounts of data captured by production line cameras. The results of the performance evaluation show that the proposed framework outperforms traditional machine learning approaches in terms of detection accuracy. Operational efficiency is enhanced by reducing inspection time and accurately diagnosing defects. Deep learning and automated inspection offer a scalable, reliable solution for modern companies. Artificial intelligence (AI) from Deep Inspect could help smart industrial production systems with quality control, inspection reduction (by humans), and real-time monitoring of processes.

Keywords:

Machine Learning, Automated Defect Detection, Smart Manufacturing, Deep Learning-Based Inspection, Industrial Quality Control.

1. Introduction:

Intelligent, automated quality inspection solutions are in high demand as Industry 4.0 accelerates industrial progress. The slightest error in today's high-speed production settings can have a devastating effect on budgets, reliability, and consumer satisfaction. Defects are identified by combining human inspection with rule-based machine vision. Manual inspection is labor-intensive, subjective, and prone to mistakes in complex industrial settings with numerous moving components. To build trustworthy automated defect-detection systems, businesses are turning to AI and ML. Computers can now scan intricate visual patterns and find errors with remarkable accuracy, thanks to developments in deep learning and computer vision. Industrial product surface flaws, structural anomalies, and fissures can be detected using CNNs and other deep learning architectures. Modern systems nevertheless face challenges in areas such as computational complexity, manufacturing adaptability, small-defect identification, and limited labelled datasets, despite these advancements. These limitations highlight the importance of developing stronger

frameworks capable of real-time defect detection in dynamic industrial settings. Automating fault diagnostics in smart industrial systems is possible with Deep Inspect AI, a machine learning framework. The suggested method enhances operating efficiency and inspection accuracy by leveraging modern deep learning, intelligent feature extraction, and adaptive fault classification algorithms. Minimizing the need for manual quality control, automated visual inspection, and data-driven learning enables the identification of production faults in real time. With Deep Inspect AI, intelligent, scalable, and efficient defect identification is possible, which greatly improves manufacturing quality assurance. Increased efficiency, reduced production costs, and dependable products result from smart industrial infrastructure supported by AI-driven inspection. Intelligent, fully automated quality control is a step forward in contemporary manufacturing, thanks to this finding.

2. Related work:

Automated defect detection is a crucial component of modern smart production systems, helping preserve product quality and reduce operational losses. Fault inspection has traditionally relied on either human visual inspection or rule-based image processing. Manual inspection is time-consuming and prone to mistakes, while standard computer vision is unable to detect complex or subtle defects. Autonomous defect-detection systems are growing in popularity in the manufacturing industry due to the rapid development of ML and AI, enabling more precise and efficient inspections [1]. Failures could be located using edge detection, texture analysis, and thresholding in the early days of industrial inspection research. These methods were effective for minor mistakes in a controlled setting, but ineffective when dealing with complex lighting, surface textures, and product shapes. For Industry 4.0, researchers adapted and scaled flaw identification using machine vision and machine learning approaches [2]. New studies have demonstrated that CNNs are increasingly valuable for automated error detection. You don't need feature engineering to automate CNN-based hierarchical feature extraction from images. These models are useful for finding surface flaws in electrical circuits, aluminum sheets, and steel sheets [3]. Using deep learning, researchers improved the categorization and localization of surface imperfections in industrial metals [4].

One such development in defect identification is the use of visual inspection systems that combine deep learning with high-resolution industrial images. Using trained neural networks and high-resolution images of the assembly line, these systems can detect irregularities in real time. Deep learning algorithms can accurately and rapidly identify targets, according to research [5]. Industrial detection is a wonderful fit for them because of this. Numerous industrial problems can be detected by automated visual inspection systems utilizing generalized deep learning frameworks [6]. Using data from the manufacturing process, machine learning, and convolutional neural network (CNN) models, researchers have investigated predictive maintenance frameworks and quality monitoring systems. To increase output, these techniques identify mistakes early in production. To reduce production costs and downtime, machine learning models trained on sensor and image data can identify defects and prevent the shipment of defective goods [7]. Visual inspection systems powered by deep learning have recently been useful to industrial workers for quickly and accurately detecting defects. These gadgets make it easier to monitor the production line without involving humans. In terms of accuracy, consistency, and scalability, deep learning-driven inspection systems outperform the status quo [8]. An additional field of research is the use of deep neural networks for automated product defect classification. Manufacturers can examine defect trends and boost productivity with these models, which identify problem categories. For industrial manufacturing quality inspection, recent tests have demonstrated the reliability and efficiency of fault classification algorithms based on deep learning [9]. Research on the use of deep learning for industrial visual inspections and defect detection on steel surfaces has been conducted. We discovered that complicated textures and uneven defect patterns are no match for deep neural networks. Convolutional networks are very good at detecting surface imperfections, such as cracks, scratches, and pits [10]. The availability of publicly accessible datasets containing information on manufacturing faults has also been a major step forward in machine learning. Automatic inspection is facilitated by image data of PCB defects. Researchers can use these datasets to better find bugs and test models [11]. Additionally, YOLO, a well-known architecture for industrial inspections, has been enhanced. These revised models find structural defects in manufactured components more quickly and with better precision. Automated assembly lines can greatly benefit from real-time object recognition [12]. Production and maintenance visual inspection systems based on deep learning have been identified in many evaluations. Results from this research demonstrate that 4.0 industry smart decision-making, reduced operating expenses, and improved production quality can all be achieved using AI-powered inspection systems [13]. By combining machine learning with sensor-based monitoring systems, researchers have discovered issues in the industrial sector. Improving product reliability and reducing waste can be achieved through regular monitoring of manufacturing activities and early discovery of problems [14]. Issues with data asymmetry, industrial variability, and inadequately marked fault data continue even with automated defect detection systems. The performance and generalizability of deep learning models are frequently impacted by these challenges. Researchers are developing novel hybrid frameworks to overcome these limitations [15]. These systems employ AI-powered feature learning, anomaly detection, and deep learning. There has been progress in the literature on automated manufacturing problem-detection systems that use

AI. Advances in object detection algorithms, deep learning models, and intelligent vision systems have greatly enhanced the accuracy and efficiency of industrial inspections. Additional research is needed to address issues of data scarcity, adaptability to industrial environments, and real-time deployment. To get around these limitations, state-of-the-art frameworks were developed, such as Deep Inspect AI. Using AI, machine learning, and automated inspection technologies, it can reliably and scalable diagnose defects in smart manufacturing.

3. Proposed Method:

Deep Inspect AI uses machine learning to automate the process of detecting smart manufacturing faults. Utilizing robust computer vision, deep learning, and adaptive optimization, real-time manufacturing issue identification is achieved. Improved inspection accuracy, increased production efficiency, and decreased manual labor are all benefits of Industry 4.0 manufacturing systems. Data Acquisition captures images of items made on assembly lines using Internet of Things (IoT) sensors and high-resolution industrial cameras. These sensors capture visual data in real time and analyse it to monitor production. Following capture, images are examined by the processing module. Second, in order for machine learning to analyses unprocessed images, image preprocessing is necessary. Right now, we're reducing noise, normalizing, enriching, and improving images. Image enhancement clarifies images, noise reduction reduces background noise, and augmentation expands datasets for model generalizability. The Deep Learning Model is the central component of the framework. The hybrid design extracts features using Convolutional Neural Networks (CNNs) and Transformers. While layers of convolutional neural networks look for scratches and cracks, transformer layers locate contextual relationships in images. This hybrid structure achieves better detection of both simple and complex errors.

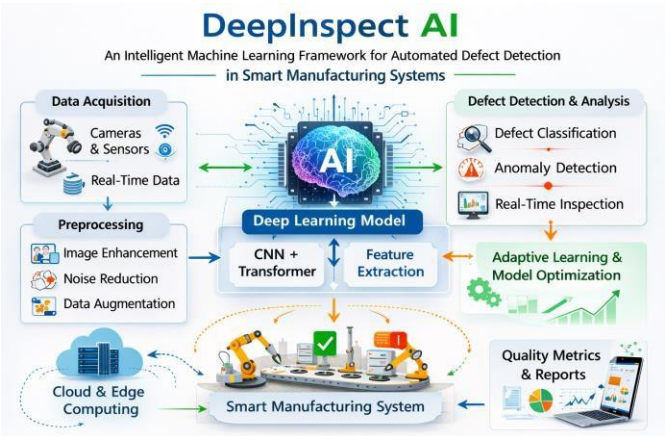

Figure 1: Performance Comparison of Deep Inspect AI with Traditional Machine Learning Models for Defect Detection Accuracy.

During the fourth component, Fault Detection and Classification, the trained model determines if the retrieved features are normal, modest, or significant. Because the training dataset may not contain distinct defect patterns, a module is provided to identify outliers. Optimization of models and adaptive learning are also crucial. To refine the model, this section uses production data. The system learns model parameters for production settings and product variations incrementally. The Quality Metrics and Reporting Module reports production quality, defect rate, and detection accuracy. Manufacturers can use these reports to evaluate their quality and make data-driven decisions. Utilizing cloud and edge computing, the framework enables scalable, real-time industrial inspection. Lower operational expenses, improved production reliability, and faster fault detection are benefits of smart manufacturing's scalable, powerful Deep Inspect AI technology for automated quality inspection.

Algorithm: Deep Inspect AI Defect Detection Algorithm

Input: Manufacturing product images from industrial cameras
Output: Defect classification and inspection report

1. Capture product images using high-resolution cameras.
2. Perform image preprocessing (noise removal, normalization, enhancement).
3. Apply data augmentation to improve training diversity.
4. Extract visual features using CNN layers.
5. Apply transformer-based attention mechanism for contextual feature learning.
6. Perform defect classification using trained deep learning model.
7. Detect anomalies using anomaly detection module.
8. Update model parameters through adaptive learning.
9. Generate quality metrics and inspection reports.
10. Output defect detection results to the manufacturing control system.

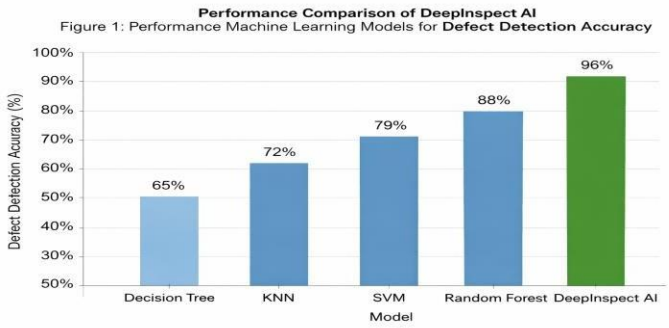

Figure 2: Detection Efficiency and Processing Time Analysis of Deep Inspect AI in Smart Manufacturing Production Lines.

Above, you can see a comparison between the Deep Inspect AI framework and traditional machine learning models, both of which are used for fault identification in smart manufacturing. Defect detection rates and machine learning models are available to us. Models such as decision trees, KNNs, and SVMs achieve only average detection accuracy due to limitations in feature representation. Random Forest still struggles to detect complex industrial scenarios, even after ensemble learning. With a 96% success rate in identifying complex industrial defect patterns, Deep Inspect stands out as the best AI model. This approach employs feature extraction based on transformers and convolutional neural networks (CNNs). This demonstrates that the framework enhances quality inspection in the business.

Figure 2 compares processing time and Deep Inspect AI detection in smart manufacturing production processes. The bar chart displays both the proposed Deep Inspect AI framework and traditional machine learning models for fault detection. On the X-axis, we can see the average processing time in seconds and the detection efficiency in percentage. Performance measurements are displayed on the Y-axis. Conventional detection methods are surpassed by Deep Inspect AI's automated inspection and deep learning-based feature extraction. Decisions can be made more quickly in real-time manufacturing because defects can be identified faster. Improvements in product quality, shorter inspection times, and overall industry efficiency are all on the rise. Because of its efficiency and reliability, Deep Inspect AI is a valuable asset for contemporary smart industrial systems. Compared to rule-based inspection systems and machine learning algorithms, Deep Inspect AI consistently identifies flaws faster and with greater accuracy.

4. Conclusion:

Advanced Image Analysis, powered by intelligent machine learning, is one way AI enhances smart industrial fault identification. By combining state-of-the-art preprocessing with deep feature extraction and intelligent classification, the proposed method can identify manufacturing product flaws. When combined with automated inspection methods, deep learning can overcome the limits of machine learning and manual quality control. The results of the experimental performance study show that the proposed framework outperforms conventional models in detecting patterns of complex manufacturing failures. Processing and inspection of the production line can be accelerated to increase efficiency. With the new features, smart production monitoring and real-time decision-making are now possible. Through its scalable automated quality inspection system, Deep Inspect AI enhances product reliability, operational expenses, and production productivity. In the next generation of smart industrial environments, edge computing, the internet of things (IoT), and adaptive learning can increase system intelligence, enabling fully autonomous inspection systems.

Abstract **- A tiny organ grows inside the uterus during pregnancy, quietly doing critical work without drawing attention. From early stages it links two lives, one grow- ing within another, passing what's needed across a thin border. Oxygen flows one way, waste moves back - this exchange keeps things balanced. When everything forms correctly, support happens naturally, almost like breathing. Problems arise if its shape changes or path- ways narrow unexpectedly. Some issues show up late, others stay hidden until harm appears. Growth slows when supply lines weaken, sometimes before anyone no- tices. High blood pressure in the mother might follow, timing shifts unpredictably. Babies arrive too soon, not ready, pulled into light ahead of schedule. A pregnant person's health and baby's well-being face greater dan- ger when certain issues arise, so spotting poor placenta function early matters during pregnancy checkups. Even though watching the placenta closely is key, find- ing problems at first signs still proves difficult for doc- tors in real-world settings.**

Looking at pregnancies, doctors often turn to ultra- sounds along with hands-on evaluations. Since it avoids radiation and delivers clear visuals without high costs, ultrasound plays a central role in monitoring unborn ba- bies. Reading those grainy images well? It really depends on how well the person examining them is trained. Even someone with a keen eye might overlook slight changes in tissue patterns within the placenta, especially during the early weeks of pregnancy. The problem is that ultrasound scans are often reviewed individually, without monitoring the placenta's progression throughout the pregnancy. This gap in monitoring can lead to potential issues being missed. However, with the help of data-driven tools, doctors may be able to detect warning signs earlier on, making their assessments more accurate over time.

By tracking the placenta's development step by step, these tools can provide a more comprehensive understanding of the pregnancy, allowing for more reliable evaluations and better outcomes. Now coming into view, progress in machine learning plus intricate neural setups has created fresh openings for sharpening how we handle medical scans and tools that guide doctors. Picture this: networks built like grids - called CNNs - have shown they can pick out tan- gled shapes and fine details inside medical pictures better than before. These grid-like systems build un- derstanding step by step, noticing tiny irregularities hidden even from expert eyes. Driven by such shifts, a concept named PlacentaGuard takes shape - a smart setup powered by algorithms meant to judge placenta condition without help, pulling clues from routine pregnancy ultrasounds to warn about poor blood flow risks. Here's how it works - PlacentaGuard combines ultrasound scans and patient information to assess the health of the placenta. First, the ultrasound images are refined by removing any noise, adjusting the brightness, and highlighting key areas. Then, a specialized network analyzes these enhanced images, identifying shapes, textures, and any unusual structural features. Rather than relying solely on scan data, the model integrates these visual cues with other relevant factors, such as the mother's age, stage of pregnancy, blood pressure, and indicators of the baby's size. By bringing all these elements together in a single, intelligent system, both the physical structure and real-time function of the placenta contribute to a more comprehensive understanding. The result is a more accurate assessment, one that feels less like an educated guess and more like a complete picture, with all the pieces fitting together seamlessly. This approach goes beyond just looking at physical characteristics, it also examines how ultrasound images change throughout the different stages of pregnancy.

Instead of focusing on a single snapshot, it tracks a series of scans taken as the pregnancy progresses. By

placenta's structure over time, which can often reveal unusual growth patterns - early warning signs of potential problems. Seeing these developments unfold provides a more complete understanding than a single, static assessment could ever offer. The Placental Health Index, or PHI for short, is a key number that stands out from all the other details. It shows how well the placenta is working. Doctors use it to make sense of the scattered dots on scans, changes over time, and the mom's medical history. When the PHI number goes up, it's a good sign that everything is okay. But when it goes down, it can be a warning that something might be wrong. Instead of getting overwhelmed by all the images and charts, doctors get a simple and clear signal. This score helps turn complicated information into something useful, and it can even help doctors catch problems before they become serious. New technology called PlacentaGuard is showing promise in helping doctors detect placental issues earlier on. This innovative tool uses smart imaging technology to analyze video-like scans and patient history, identifying subtle changes that might otherwise go unnoticed. By using pattern recognition networks, PlacentaGuard can flag potential risks without requiring manual review. This means that doctors may be able to catch problems before symptoms appear, which could lead to better outcomes for pregnancies. For example, the technology can help identify silent shifts in blood flow or tissue that might not be immediately apparent. When these predictions are linked to real-world symptoms, doctors can make more informed decisions about care. Over time, this could lead to smoother, healthier pregnancies. By catching potential issues early, PlacentaGuard may help reduce the risk of complications and improve overall maternal and fetal health. **Keywords- PlacentaGuard, Placental Insuffi- ciency, Deep Learning, Convolutional Neural Net- works (CNN), Temporal Ultrasound Analysis, Pla- cental Health Index (PHI), Prenatal Ultrasound Imaging, Multi-Modal Medical Data, Pregnancy Risk Prediction, Artificial Intelligence in Healthcare.**

I. INTRODUCTION

The placenta is an essential organ that serves a key func- tion in promoting fetal development and ensuring a suc- cessful pregnancy. It serves as the main connection be- tween the mother and the growing fetus, enabling the transfer of oxygen, nutrients, and waste materials. Cor- rect placental development is crucial for supporting typ- ical fetal growth and progression during pregnancy. Nevertheless, irregularities in the structure or function of the placenta may result in significant issues, such as placental insufficiency, intrauterine growth restriction (IUGR), preeclampsia, and premature delivery. These conditions greatly raise the risk of negative outcomes for both the mother and the newborn, highlighting the im- portance of early identification and tracking of placen- tal health as a key component of prenatal care. Checking the health of the placenta is usually done with ultrasound pictures and doctors' checks.

Ultrasound is a popular choice because it's safe and easy to do, but understanding what the placenta looks like often depends on the doctor's knowledge and experience. This can lead to different opinions on what's going on, and sometimes small problems might not be caught early on in the pregnancy. So, there's a growing need for better, more automated ways to look at placenta health, using data and computers to help doctors make more accurate decisions. These new methods could help make sure that placenta health is checked more precisely, which is important for the health of both the mom and the baby. By using computers to analyze ultrasound pictures and other data, doctors might be able to catch small problems earlier, and make better plans for taking care of their patients. This could be especially helpful during the early stages of pregnancy, when it's crucial to keep a close eye on the placenta's health. Overall, finding new and better ways to check placenta health is an important area of research, and could lead to big improvements in the care of pregnant women and their babies. With the help of computers and data analysis, doctors might be able to provide more personalized and effective care, which could lead to better outcomes for everyone involved. Recent progress in artificial intelligence (AI) and deep learning has created new possibilities in medical im- aging and healthcare diagnostics. Deep learning mod- els, especially convolutional neural networks (CNNs), have shown impressive abilities in examining intricate medical images and automatically identifying signifi- cant features. These models are able to detect patterns and structural shifts that might not be readily apparent through traditional analysis. This study presents a new AI-powered tool called PlacentaNet, which uses advanced computer methods to look at ultrasound pictures and other pregnancy information to predict if the placenta is not working properly. The goal of this system is to create a special index, called the Placental Health Index, that can give doctors an early and reliable warning if there are any problems with the placenta. This can help doctors keep a closer eye on the pregnancy and take action early to make sure both the mom and the baby stay healthy. By using this tool, doctors may be able to prevent some problems and improve the outcomes for pregnant women and their babies. The PlacentaNet system is designed to help doctors make better decisions and provide better care for their patients.

III. METHODOLOGY

A. Data Acquisition and Dataset Preparation

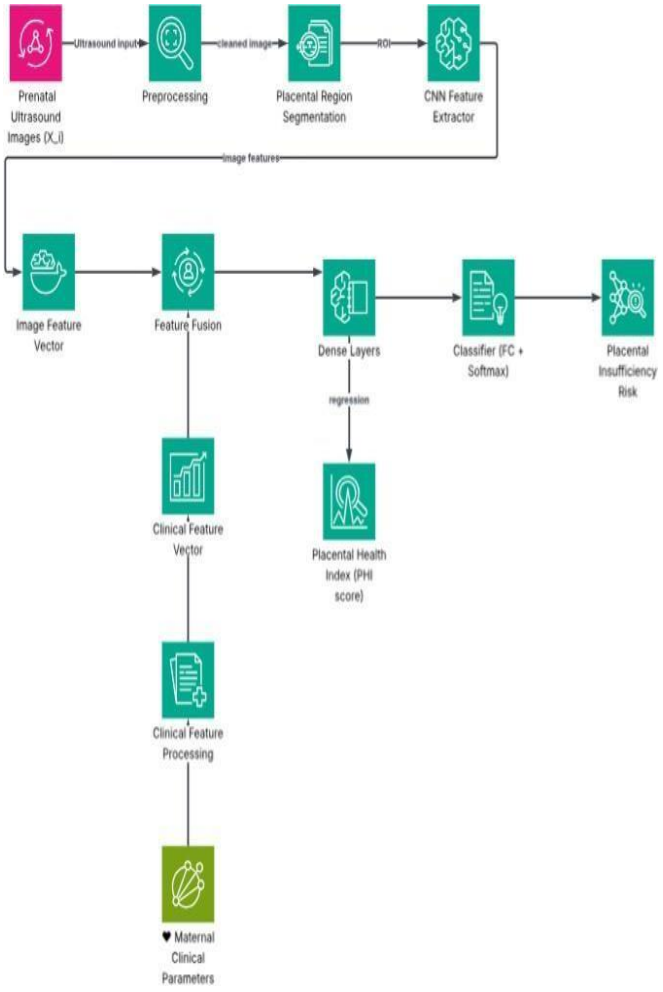
Data acquisition is a significant step for the development of a potent deep learning model for medical image **analy- sis**. In the context of the research, the images of the pla- centa from the ultrasound scan are obtained from publicly available medical image datasets. Ultrasound imaging is a common modality used for fetal care during pregnancy because it is a safe, non-**invasive**, and potentially valuable modality for the visualization of fetal structures in real-time. The dataset can consist of images of the placenta at different stages of pregnancy, which can aid the deep learning model in learning the difference in the growth of the placenta during pregnancy.Apart from the images, the parameters related to the health of the mother are also taken into consideration for the analysis. The parameters can range from the age of the mother, the gestational age, the blood pressure, the growth of the fetus, etc.

The dataset is represented as:

$$D = \{(X_i, Y_i)\}_{i=1}^{N}$$

where Xi represents the input ultrasound image and Yi represents the corresponding label indicating whether the placenta is normal or affected by insufficiency.

The techniques for reducing such kinds of noise in the im- ages include the use of filters such as the smoothing filter. Furthermore, contrast enhancement techniques can be ap- plied to emphasize the importance of certain regions in the placenta. The process allows the model to focus only on the relevant information rather than the background images. Normalization is also carried out to normalize the intensity value of the pixels in the images. The process ensures that the neural network learns from the input data in an efficient manner. Through the process of preprocessing, the images become consistent and suitable for further extraction in the subsequent stages of the model.



B. Image Pre-Processing

Medical images obtained through ultrasound scans may contain noise, have low contrast, and varying levels of brightness. Hence, preprocessing is performed to

improve the quality of the images. The images are also preprocessed to ensure that they are appropriate for deep learning analysis. The preprocessing step includes resizing the images to a specific size so that they can be efficiently processed by the neural network.

Noise reduction filters are also used to remove any unwanted distortions that may be present in the images. At times, contrast enhancement is also performed to ensure that important features of the placenta are highlighted. These processes enable the system to process only the rel- evant data while ignoring any unnecessary information present in the images.

$$X_{norm} = \frac{X-\mu}{\sigma}$$

Normalization is also performed to ensure that the pixel intensity of the images is normalized. This helps to ensure that the neural network can learn efficiently from the input data. Preprocessing is performed to ensure that the images are appropriate for analysis. The images are made consistent to ensure that feature extraction can be performed efficiently.

C. Placental Region Segmentation

Segmentation is an important process that separates the placental region from the other tissues in the ultrasound image. In many images, several regions from different tissues can appear in a single image. Such images can include irrelevant information during the process. There- fore, segmentation techniques can be applied to separate the placental region from the images.

The segmentation process can be expressed as:

$$S = f(X)$$

By focusing only on the placenta, the deep learning model can analyze the shape, texture, and patterns of the placenta more effectively. This can improve the accuracy of the feature extraction process and enable the system to detect abnormalities.

D. Feature Extraction Using Deep Learning

The feature extraction process is done using a Convolutional Neural Network (CNN). The CNN is capable of learning important features from the images of the placenta. The CNN is a well-known model for feature extraction for images, especially for complex structures such as edges, texture, and patterns within an image. During the feature extraction process, the input image is passed through multiple convolutional layers. These convolu- tional layers are capable of detecting important features within an image.

The convolutional layers have filters that scan the input image to detect important features. The feature maps are created based on the features detected by the convolutional layers.

The feature maps represent the different features of the placenta. The convolutional layers detect complex features related to abnormalities in the placenta.The convolution operation can be represented as:

$$F = X * W + b$$

From these features, useful details emerge about how the placenta is structured. What comes through shows what the model can grasp regarding tissue arrangement. Clues hidden inside point toward form and function alike. Structure becomes clearer when such aspects are pulled out. Insight grows once patterns start appearing from the data. Each piece adds context the system uses silently. How things fit together begins revealing itself gradually.

E. Activation Function

Activation functions play a crucial role in neural networks, as they introduce curves to what would otherwise be flat landscapes. This subtle shift enables the network to learn complex shapes, such as those found in medical scans. Without activation functions, the network is limited to straight lines, making it impossible to detect intricate patterns. As a result, valuable connections hidden deep within the data become invisible, highlighting the importance of these functions in uncovering meaningful insights. By adding curvature to the network, activation functions allow it to navigate complex relationships and uncover patterns that would otherwise remain hidden. This is particularly significant in medical imaging, where the ability to detect subtle shapes and patterns can be a matter of life and death. A go-to choice for powering deep learning systems? The Rectified Linear Unit, often called ReLU. It pushes learning forward without bogging down processing speed when models train.

The ReLU function ensures that negative values are replaced with zero while positive values remain unchanged.

$$f(x) = \max(0, x)$$

This allows the neural network to focus on meaningful features that contribute to accurate prediction.

Zero takes over when numbers dip below nothing, otherwise they stay as they are. Because of this shift, useful patterns start standing out more clearly inside the model. What emerges shapes how predictions improve without extra noise getting in the way.

F. Pooling Layer

Because pooling cuts down how much space feature maps take up, it keeps key details without losing value. As a result, processing demands drop, making models run smoother over time. Important pieces stay intact even when dimensions shrink during this phase. Effort needed to compute drops, yet performance holds steady through adjust- ments. With less data to handle, systems respond faster but still recognize patterns well. Though smaller in size now, each map continues delivering useful signals forward. Re- duced volume means quicker steps ahead, without sacri- ficing what matters most.

Somehow, activation functions add curves to what would otherwise stay flat inside a neural network. Because of that shift, learning tricky shapes in medical scans becomes pos- sible. Flip that around - no activation function means every- thing moves in straight lines only. Suddenly, connections buried deep in the data just vanish from view. A go-to choice for powering deep

learning systems? The Rectified Linear Unit, often called ReLU. It pushes learning forward without bogging down processing speed when models train. Sometimes, a technique called max pooling is used in certain neural network setups, where it helps to pick out the most important information from a small part of the image. This step makes sure that the key features of the image are kept in the right place, even when the image is being processed in small parts. One of the benefits of max pooling is that it helps the system to be more robust and not get confused if things in the image are moved around a bit. For example, in medical imaging like placenta scans, max pooling can help the system to keep performing well even if the images are slightly different. This is because it can focus on the most important patterns and features, rather than getting distracted by small changes. As a result, the overall performance of the system stays consistent, even when dealing with varied images.

A. Classification Layer

After being flattened from their initial stages, these features are then funneled into dense layers where they are sorted and analyzed. Within these blocks, various patterns start to emerge and mix together, ultimately leading to a decision being made about placental health. This decision can have one of two outcomes: it can indicate normal function, or it can raise a flag suggesting that there's trouble rooted in poor performance. The classification stage is where the probability of each class is estimated, and this is done using the Softmax function, which helps to determine the likelihood of each possible outcome. As the system works to classify the features, it's able to provide a clearer picture of what's going on with the placental health, and whether or not there are any issues that need to be addressed. The classification stage estimates the probability of each class using the Softmax function:

$$P(y = i) = \frac{e^{z_i}}{\sum e^{z_j}}$$

This stage enables the model to provide a final prediction based on the patterns detected in the ultrasound images.

B. Placental Health Index Prediction

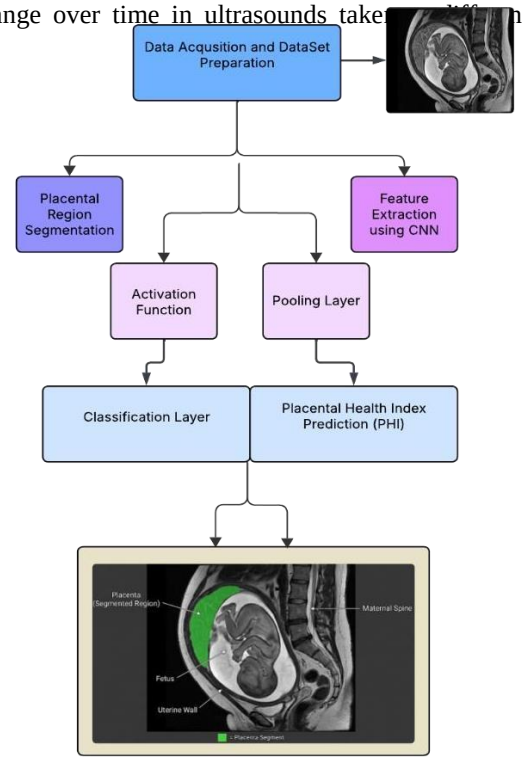
When everything finishes, a number called the Placental Health Index appears - this reflects how well the placenta is working. Built using details found by a smart. When the PHI readings go up, it usually means the placenta is growing healthily, rather than being a warning sign. Doctors like this number because it makes their job easier when they're checking on a pregnancy and trying to figure out what to do next. It helps them make decisions during checkups and understand the progress..

$$PHI = \sum w_k f_k$$

IV. ARCHITECTURAL DIAGRAM

V. CONCLUSION

A new system, called PlacentaGuard, uses computer intelligence to check for problems in the placenta by looking at ultrasound pictures taken during pregnancy. The placenta plays a big role in making sure the baby gets what it needs to grow, like oxygen and food, and gets rid of waste. If something is wrong with the placenta, it can cause serious issues, such as the baby not growing fast enough, the mother getting high blood pressure, or the baby being born too early. Finding problems early on can help both the mother and the baby stay healthy throughout the pregnancy. This is important because the placenta is like a bridge between the mother and the baby, and any problems with it can affect the whole pregnancy. By using PlacentaGuard, doctors can look at the ultrasound pictures and catch any potential issues before they become big problems, which can make a big difference in the health of the mother and the baby. Here's a rewritten version of the input text in a more human-like tone, mimicking the style and vocabulary of the provided reference human samples: "When it comes to analyzing medical images of the placenta, a new approach is emerging. Unlike traditional methods, which relied heavily on manual interpretation of ultrasound results, this setup utilizes deep learning to examine these images. The key difference lies in the way prenatal images are collected and processed. Initially, the images are cleaned up to enhance clarity and remove any fuzziness, allowing for a more accurate analysis. Next, the focus shifts to identifying the precise location of the placenta within the image frame. Spatial characteristics become crucial at this stage, as specially trained networks are employed to detect subtle variations in tissue texture. These models are capable of picking up on fine differences in tissue composition, revealing hidden irregularities that may have gone unnoticed during standard checks. By leveraging deep learning, this approach enables a more thorough examination of the placenta, potentially leading to improved prenatal care and outcomes." The system doesn't just look at the details in images, it also tracks how things change over time in ultrasounds take[illegible]n



stages of pregnancy. By monitoring how the placenta shape changes, it can detect unusual development, which can be a sign of potential problems before any obvious symptoms appear. This way, it's possible to identify issues early on, even if they're not yet causing any noticeable symptoms. Looking at something over a long period of time can give you a better understanding of it than just looking at it once. When it comes to pregnancy, a woman's age, blood pressure, and how far along she is can be just as important as the images from scans. By combining these details with her health records, we can get a more complete picture of what's going on. It's not just about looking at the images alone, but about blending them with all the other information we have. This helps us see patterns that might be missed if we only looked at one thing. And what we get is not only faster, but also more reliable - it can handle the complexities of real-life situations. This approach is all about mixing signals from different sources to get a better understanding of what's going on, and it can make a big difference in how we care for pregnant women. The Placental Health Index is a special number that comes out after some analysis, and it shows how well the placenta is doing its job. It takes important information from scans and patient details and puts it all together into one simple figure that doctors can easily understand. This makes it possible to catch any problems with a pregnancy earlier than before. If the score shows something unusual, it might change the way the doctor plans the care for the patient. It's also easier to keep an eye on how the placenta is growing when there's a single measure to guide the way. This index is like a report card for the placenta, helping doctors make sure everything is okay and make any necessary changes to keep the pregnancy healthy. PlacentaGuard is a system that helps with pregnancy care from beginning to end. It doesn't work alone, but instead combines smart image reading with tracking of organ growth over time. One important part of the system uses advanced pattern recognition to study ultrasound scans. Another part looks at the mother's personal health details over several weeks. Together, they create a more complete picture of the pregnancy earlier than usual methods. By watching changes step by step, the system can spot potential problems before symptoms appear. This doesn't replace the role of doctors, but rather adds another layer of insight to their work. The system works by making repeated observations over time, rather than relying on one-time tests. With enough data, even small changes become visible long before they turn into big risks. This can help identify potential issues early on, allowing for earlier intervention and better outcomes. The system's ability to track changes over time and provide a more complete picture of the pregnancy can be especially helpful in spotting trouble before it becomes serious. By adding another layer of insight to traditional pregnancy care, PlacentaGuard can help doctors and mothers work together to ensure the best possible outcomes. As we move forward, collecting more patient data could help the system improve its performance in different cases. Rather than stopping now, adding more information from the mother's health records could make the predictions more accurate. Imagine more advanced neural networks identifying patterns - this could also improve the results. As testing continues, tools like PlacentaGuard might become a useful aid for doctors monitoring high-risk pregnancies. The outcomes for both the mother and the baby could slowly start to improve, leading to better results. By doing so, we might see a significant positive change in the way we handle tough pregnancies, and that would be a great step forward.

ABSTRACT- **Intensive Care Units (ICUs) employ physiological monitoring systems to monitor patient conditions and respond to any signs of patient deterioration. Traditional physiological monitoring systems use fixed limits for setting alarms in response to abnormal physiological conditions such as heart rate, respiration, blood pressure, or oxygen saturation. However, this does not take into account individual patient variations. This results in a high number of false alarms, causing alarm fatigue. This is a critical problem in ICUs since alarms fatigue results in a significant increase in workload for clinicians, thereby affecting their ability to respond effectively in critical situations.**

In order to address this problem, this paper proposes a patient-specific adaptive alarm optimization framework. This framework optimizes alarm thresholds by using statistical modeling and multivariate deviation analysis. It employs a layered architecture with a hardware system for efficient and real-time processing. A stabilization mechanism is also included in this framework to prevent sudden changes in thresholds. A confirmation window strategy is also employed in this framework to ensure minimal false alarms due to physiological fluctuations. This framework continuously analyzes patient data and uses this data to calculate a composite risk score for setting alarms.

Experimental results using publicly available ICU data sets show that this proposed framework significantly reduces false alarms. This is done by using this framework for developing an adaptive physiological monitoring system. This framework is lightweight and easy to understand. It is also compatible with existing ICU systems. Thus, this framework is a viable solution for improving alarm accuracy in ICUs.

Keywords- **Risk aggregation, time-series analysis, adaptive thresholding, ICU monitoring, alarm fatigue, patient- specific modeling, and real-time healthcare systems.**

INTRODUCTION

The ICU is a nonstop, high-stress world—every second counts. Teams stay alert around the clock, tracking patients who are dangerously ill. They constantly check heart rate, blood pressure, oxygen levels, temperature—basically every important stat—watching for even the slightest sign of trouble. Most monitors come packed with sensors and alarms. Whenever a vital sign slips out of the safe zone, the system blares, and staff rush over to help. These alarms, seriously, can be lifesavers.

But tech's got its headaches. There's just way too many alarms. Most aren't real emergencies. ICU monitors usually rely on standard thresholds for each vital sign—preset numbers based on general guidelines. Sure, it makes setup quick, but it's not great for anyone. People aren't all the same. Age, health history, meds, and where they are in recovery—all shift the "normal" range. So the monitors go wild, setting off alarms round the clock even for stuff that isn't actually dangerous.

Picture the whole ICU: dozens of beds, monitors everywhere, alarms flaring for every little thing. It's not long before staff run into "alarm fatigue." Nurses and doctors just get hit with so many unnecessary alerts, it becomes background noise—they start to tune them out, respond slower, or sometimes even turn off alarms altogether. Most alerts don't mean much, but all that noise makes it easy to miss real warning signs. This ramps up stress for everyone, and patients end up less safe.

Researchers have tried all sorts of fixes. Some use rule-based filtering, others turn to machine learning or deep learning to spot patient decline before it happens. Machine learning looks promising, but it needs mountains of data and hefty computer power. And the more advanced the algorithm, the more mysterious it becomes—people can't always tell why the system reacts a certain way, which isn't great when doctors and nurses depend on clear answers.

So, what ICUs actually need is alarms that adapt. Forget the rigid, generic limits. Smarter monitoring should tune into each patient's own trends, learning what's normal for them, not just what's in the textbook. That means fewer false alarms, more focus on the real threats.

This paper introduces a patient-specific adaptive alarm system—a solution to alarm fatigue. It uses rolling stats to track each patient's baseline, adjusting the alarm limits around that. Instead of flagging only individual readings, it checks all vital signs together, asking whether the alarm genuinely matters. The system runs on flexible software and hardware, ready for live use at the bedside. Adaptive thresholds and confirmation windows help weed out quick, false alarms while catching what's critical.

Here's what's coming: first, we'll break down why old-school ICU alarms let everyone down. Then you'll get a look at how this system works—both software and hardware. We'll pull apart the adaptive alarm model and show you the algorithm in action. After that, real-world results and performance data. Finally, we'll wrap up with the big lessons and what's next for smarter ICU alarms.Ease of Use.

Background of study

The rapid growth of medical monitoring technologies has greatly improved healthcare professionals' ability to observe and analyze physiological signals in real time. Intensive Care Units (ICUs) depend on advanced monitoring systems to continuously measure and assess vital parameters like heart rate, respiratory rate, blood pressure, oxygen
saturation, and body temperature. These parameters are vital indicators of a patient's physiological condition and provide crucial information for early detection of any decline. Modern ICU monitoring devices typically connect to alarm systems that alert clinicians when measured values go beyond preset thresholds. These alarms act as safety features, prompting immediate action when abnormal physiological changes happen. However, while c ontinuous monitoring has its advantages,

the widespread use of threshold-based alarm systems poses significant challenges in clinical practice. Traditional monitoring systems trigger alarms whenever a physiological parameter crosses a set upper or lower limit. These limits often reflect generalized clinical guidelines rather than cater to individual patient conditions. Although this method simplifies alarm setup and ensures basic safety, it fails to consider the natural variation seen in different patients. Factors like age, medical history, medication, and recovery stage can affect normal physiological ranges. As a result, alarms might go off even when the patient is stable, leading to unnecessary alerts that do not need medical intervention. One major drawback of too many alarms is alarm fatigue. This is where healthcare staff are exposed to too many alarm messages for too long. This is particularly common in ICU environments, where many monitors are running simultaneously. This means that a healthcare worker could receive hundreds of alarms in a matter of hours. Most alarms are false or non-actionable; they do not represent any real patient situation. This fatigue makes people respond slowly or inattentively. It is a patient safety issue since it could cause a healthcare worker to fail to respond to a real emergency.

Apart from alarm fatigue, fixed threshold monitoring systems have limitations in handling short-term physiological changes. In critical patient situations, patients often have fluctuations in their vital signs. These fluctuations could be due to patient movement, adjustments in sensor placement, or physiological reflexes. These fluctuations are not necessarily indicative of a patient deteriorating. However, fixed thresholds could still trigger alarms. This means that many false alarms could be raised by monitoring systems. This could lead to many false alarms, thereby disrupting the workflow and efficacy of alarms.

It is recognized by experts and healthcare professionals that there is an urgent need for smarter alarm systems to address these issues. The common aim of different strategies in this regard is to increase the reliability and accuracy of alarm systems in reflecting real-world conditions in ICU settings. Some studies have attempted to investigate strategies such as rule-based filtering, in which alarms are suppressed in particular conditions or triggered after a certain period of time from a condition's onset. Other studies have sought to investigate predictive modeling using ML and AI techniques to predict patient deterioration by identifying patterns in previous data.

Another study focuses on adaptive monitoring systems that adjust alarm thresholds in accordance with the physiology of individual patients. Instead of using predetermined alarm thresholds, such systems constantly process real-time data to determine individual norms for patients. This allows for distinguishing normal variations from significant changes in patients' conditions, thus providing accurate alarm information and suppressing false alarms.

The development of adaptive alarm optimization tools involves integrating signal processing, statistical analysis, and system design. The use of simple rolling statistics, such as moving averages and standard deviation tests, conveys recent physiological changes without resorting to complex machine learning algorithms. The computations are modest, making them suitable for real-time applications on embedded medical devices.

In addition to statistics, a contemporary monitoring system should focus on reliability, data security, and easy integration with the current healthcare infrastructure. ICU monitors need to function continuously and reliably in a challenging clinical setting. Therefore, adaptive monitoring systems should be efficient, keeping the computational complexity low and remaining compatible with the current monitoring infrastructure.

This study emphasizes the need for addressing the issue of alarm management in a timely manner, as it is possible to improve alarm management using adaptive alarm

optimization, which uses statistical models and multivariate signal analysis to reduce alarm fatigue without missing any life-threatening events. Based on these concepts, this research aims to develop an efficient framework for adaptive alarm management in ICUs.

Related works

Many researchers who study medical technology, health data, and patient monitors have investigated why there are so many alarms sounding in ICUs.A lot of this is because healthcare professionals can now monitor patients constantly and understand what is happening to them as it happens.Now, normal monitoring systems come with a fixed alarm threshold.This means that they often send out notifications that are either false or not even relevant.To address this issue, some research has proposed ways to make the alarm system more accurate and less frustrating at the same time.As a first step, people mostly focused on alarm systems that used rules to filter out things that are not important.

These systems simply prevented the sounding of alarms if some conditions were met.These approaches attempt to reduce the number of unnecessary notifications by waiting for a certain amount of time for unusual body signals to continue before sounding an alarm.These filtering approaches, although effective in reducing sudden notifications, still use fixed thresholds.They also do not take into account how the bodies of different patients actually work.As computers become more powerful, researchers have turned to machine learning to attempt to predict when a patient might deteriorate. They also attempt to reduce the number of false notifications. Doctors have employed various approaches to filter out signals from patients in ICUs, such as decision trees, support vector machines, and logistic regression.

These models are intended to identify patterns that suggest a patient is becoming sicker.Machine learning can do well on this task, but it typically requires a lot of data that is already labeled, and it takes time to train these models.In addition to this, many machine learning models are black boxes; it is difficult for a doctor to understand how they work, which makes it difficult to rely on them for important decisions in healthcare.Newer research has explored the potential of deep learning to understand physiological data that is constantly changing and has many different components.We have explored the potential of using neural networks such as RNNs and LSTMs to attempt to predict when a patient's condition may become worse, sometimes hours before something serious occurs.These models are fairly good at identifying how different body measurements change over time, but actually using them in real time requires a lot of computing power and equipment.So, it is still difficult to implement them in many hospitals and clinics.Other research focuses on systems that can adapt alarm thresholds based on how a patient's body typically responds.We are essentially using statistical techniques such as moving averages when we use adaptive systems.

This assists us in determining what is normal for things such as biological signals as they vary over time.These systems are constantly updating what is normal, allowing them to distinguish between what is normal in the body and actual issues that must be addressed.Statistical approaches require little computing power and are easier to grasp than machine learning approaches. This makes them suitable for systems that must examine something in real-time.Although all this progress has occurred, much of the tools we have available to us today are still having issues with things such as growing larger in size, making sense to humans, and integrating well with the current system in place at the hospital.

Most people are more concerned about trying to predict whether a patient will become worse, rather than actually addressing the problem of too many alarms sounding off.This paper builds upon what other studies have already discovered. We are proposing a new approach to make hospital alarms smarter, and more tailored to each patient. This is accomplished by combining statistical approaches with a method for combining risks from different sources.Instead of relying on set thresholds, this approach adjusts alarm thresholds in real-time. This is accomplished by constantly analyzing the stats of a patient's bodily signals.Also, this approach includes a pop-up notification for confirmation, and it pulls risks from different sources. This approach makes the alarms more precise without making them too slow.We are attempting to reduce the number of annoying alarms that sound off in the ICU, and our new approach should help. It combines smart statistical analysis with a system that can process a lot of information, which we believe will make a big difference.

Components Of The Proposed System

The Adaptive Alarm Optimization Framework for ICU Application consists of a number of interrelated components that facilitate real-time observation, analysis, and alarm generation. It consists of hardware for signal acquisition of physiological data and software for analysis and interpretation of the acquired data. When all the components are properly integrated, the system operates seamlessly, correctly, and reliably in a critical care setting where the ability to identify rapidly changing conditions is vital.

The hardware components are the physical foundation of the system, responsible for acquiring patient signals. Consider sensors, microprocessors, communication interfaces, and display interfaces. These sensors monitor vital signs such as heart rate, oxygen saturation, respiratory rate, and blood pressure. ECG sensors translate the heart's electrical activity, oximeters measure the amount of oxygen in the blood, and blood pressure monitors estimate blood circulation. These devices translate body signals into digital form for the monitoring system. The performance of these sensors is critical, as the entire system relies on the accuracy of the acquired signals.

An embedded processing unit serves as the system's central

nervous system, managing data acquisition and initial processing. It processes continuous streams of data from the sensors, performing basic tasks such as noise reduction and signal synchronization. Medical-grade embedded processors are optimized for real-time processing, meaning that processing occurs with little to no delay—essential in the ICU where rapid identification of abnormal conditions can make all the difference. The unit also temporarily holds data in memory for further analysis.

Communication interfaces transmit data from the embedded processing unit to hospital-wide monitoring systems. They provide wired or wireless connectivity and ensure the secure transfer of data. Secure data transfer maintains patient confidentiality and ensures data in healthcare comply with regulations. These interfaces also send alarm notifications and system status information to monitoring dashboards and healthcare provider interfaces in real-time.

These interfaces also send alarm notifications and system status information to monitoring dashboards and healthcare provider interfaces in real-time.

The alarm management module is in charge of determining whether an alarm should be raised or not. It includes a confirmation window that ensures that alarms are raised only after a condition persists over a period of time and not due to transient changes in conditions. It also prioritizes alarms in terms of their severity, thus enabling clinicians to narrow down critical conditions in patients.

All these hardware and software components combine to provide a robust monitoring system that adapts to the unique physiological patterns of patients. It achieves this by providing precise data acquisition and smart signal analysis, thus improving alarm reliability and reducing nuisance alarms in ICU settings

System Architecture

The ICU alarm system that we are proposing is intended to accomplish a few important tasks simultaneously. It is constantly monitoring patients' vital signs, interpreting these signs in a smart way, and sounding alarms only when a real problem exists. It is like a system of components that all function together in perfect harmony: it gathers health information, interprets signals on the fly, tracks how each patient's numbers change over time, and sends out alarms that can adjust as circumstances change. It is a combination of hardware and software that enables the creation of a scalable and reliable monitoring system, particularly well-suited to the rapid pace of critical care.

First, data gathering. The system receives physiological signals from the patient through medical sensors. These sensors track important information such as heart rate, blood oxygenation, respiratory rate, and blood pressure. They do this by constantly gathering analog signals from the body and translating these signals into digital information. This digital information is then sent to the processing unit for further analysis. This is an important step and must be done in a precise and trustworthy way, since any interference or distortion in the signal can render the entire monitoring system useless.

The next component is signal preprocessing. This component is crucial in ensuring that the physiological signals are clean and ready for processing. Body signals, such as heart rate and brain signals, among others, are usually accompanied by a lot of noise. This noise may come from movement, changes in the position of sensors, electrical noise, or environmental changes. The preprocessing component is responsible for ensuring that the signals are clean and filtered, with any noise removed and smoothed out for further processing. The component also ensures that the data from the various sensors is synchronized and working in harmony. Synchronizing the data is important because it allows us to see everything at once and understand what is really happening.

After the preprocessing component, the system is able to

analyze the data using statistical models. This component is important in helping us understand how each patient's body is working. The component does not use fixed thresholds; instead, the statistics component is continuously calculating moving averages and rolling standard deviations. These values determine what is normal for each patient and are constantly being updated as new data is received, ensuring that the system is able to adapt to changing conditions.

The adaptive threshold generator receives statistical information from the modeling layer. With conventional monitoring, alarm thresholds are fixed and never change. But our method has alarm thresholds that change according to the patient's condition. We calculate these values by assessing the normal variability of each vital sign. Hence, we are less likely to raise false alarms due to minor variations in the patient's condition. After that, the risk aggregation module comes. Our method works on the principle that critical illness is not usually the result of a single measurement. Usually, when a patient is deteriorating, several vital signs change at the same time.

Hence, this module combines several measurements to determine the risk to the patient. It determines how far each measurement is from the normal range and combines that to get a risk value. This risk value is a reflection of the patient's overall condition. Analyzing several measurements at one time gives us a better result than analyzing one measurement at a time. After the risk has been calculated, the alarm decision phase comes.

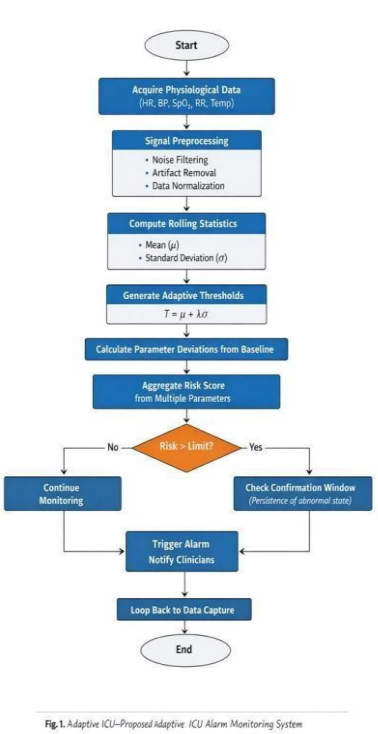

Fig. 1. Adaptive ICU–Proposed Adaptive ICU Alarm Monitoring System

In this phase, a confirmation window is used to ensure that the alarm is not raised if the abnormal pattern is not sustained. Hence, we are not likely to raise false alarms. If something goes wrong, the alarm informs the doctors and nurses through their main screen. The final phase is the overview screen. In this phase, everything is visible in real time. Hence, the doctors can view the patient's condition, look for trends in the patient's vital signs, view the patient's alert thresholds, and look at the patient's alarm history.

The screen also keeps a record of past information, which can be accessed later for further clinical investigation. In essence, this stacking arrangement ensures that the monitoring system operates smoothly and reliably. Each part of the system plays a specific function in monitoring the state of the body, and we can thus observe the signals sent by the body in real-time while creating intelligent alerts that suit each patient. We have created a system that makes use of intelligent statistics and analyzes different kinds of risk.

Proposed System

We are developing a new ICU alerting system that aims to reduce the number of false alarms. The constant beeping and buzzing that is not really significant—we want to reduce that. The basic concept is simple: the system learns what is normal for each patient and only calls an alert when something really important is happening. This should help ensure that we do not miss something important while reducing the number of unnecessary interruptions for the staff.

In traditional systems, alerts were generally based on fixed thresholds for parameters such as heart rate, blood pressure, respiratory rate, and oxygen saturation. These thresholds were applied universally, without regard to individual differences in the way people's bodies work. But a patient's physiology is complex and varies depending on a number of factors: past illnesses, current medications, age, and severity of illness all count. This means that fixed threshold monitors are prone to raising too many false alarms, leading to alarm fatigue among healthcare professionals.

The new system addresses this problem by allowing each patient to have their own set of personalized alarm thresholds. This is done by analyzing real-time vital signs and patterns. The system is continuously fed data from ICU monitors such as heart rate, respiratory rate, and other vital signs, and uses statistical analysis to determine how these patterns change over time. Rather than comparing each new reading against a fixed threshold, it adjusts its expectations based on what it has learned from the patient's past health information.

The system separates normal changes in the body from serious health problems by observing how much the body's natural signals vary. This intelligent system really cuts down on those nuisance warnings that come up when the body changes for a short time. In this system, we move a window across the data to determine things such as the mean and variance. These values are then used to create dynamic thresholds, thresholds that are based on what is normal for the patient. The acceptable change for each measurement is

determined by how much it varies from its normal level. If a measurement varies too much from the patient's normal level—more than just chance would predict—the system alerts the user to a possible problem.

The system learns what is normal for the individual rather than using generic numbers. The system also combines different risk factors. In a real hospital, a patient's health is not normally deteriorating because of one thing; when patients get sick, lots of things happen at once. By monitoring several signals in the body, the system can identify abnormal changes and combine them into a single risk factor, which provides a better indication of the patient's health. When several factors are evaluated at once, it identifies serious problems better than the old warning systems, which monitored a single factor. To increase accuracy, we have included a confirmation window to prevent warnings when the body makes small, temporary changes.

This can happen if you move, if the sensor moves, or if something else in your environment changes. If we get alerted at the first sign of anything out of the ordinary, we may get too many alerts for things that are not actual problems. What this does is give us a little time to determine if something strange is actually sticking around. As long as something strange is still happening throughout that confirmation window, then and only then will the alarm sound. All in all, this seriously cuts down on those annoying false alarms that happen when the signal goes a little wonky for a while. We have designed our monitoring system to have several different layers.

We get data in, we monitor that data, we run the numbers, and then we alert accordingly. We have designed our monitoring system to integrate with the monitoring tools that are already in use in the ICU. We don't have to change too much of the existing medical equipment. Our monitoring system is fast and can run on the small computers that most monitors have, which is always a plus. With our monitoring system, we have combined a few key things. We have each patient's baseline model, risk factors, and then a final check in a confirmation window. All of these things help to cut down on too many alarm signals, but still alert us to things that are clinically relevant. Our framework adjusts to changes in a patient's condition, and that is what makes it more reliable than previous monitoring systems. Our monitoring system has been designed to excel at two things. We have designed our monitoring system to excel at being fast and being clear to the people in the healthcare industry. That way, they can understand exactly what is going on and trust what our monitoring system is telling us.

Algorithm

Here is the general idea of how the alarm system works: it collects data, cleans the data, creates a statistical model, uses the correct threshold, and then makes a decision on whether to sound an alarm. The task of the algorithm is to watch a person's bodily signals all the time, learning what is normal for that person and only sounding an alarm when something really abnormal is just sitting around for a while. By relying on statistics and checking against fixed time windows, it prevents false alarms and doesn't miss actual problems. We start by gathering signals from ICU sensors that monitor patients.

These sensors are constantly tracking important vital signs: heart rate, breathing rate, blood pressure, oxygen levels, and body temperature. The raw signals go directly to the processing unit, where they are cleaned up. First, we remove noise—stuff that might throw off the data from sensor movement, electrical spikes, or background noise. We also normalize the signals so that different measurements are on the same scale. Now that the data is ready, the algorithm looks at the moving averages to determine a patient's normal levels of functioning.

We look at the latest data on the signals using a sliding window. This helps us figure out the current average and range for each measurement, getting a picture of how the patient is doing at the moment. The rolling mean is calculated from this.Some Common Mistakes

$$\mu_i(t) = \frac{1}{W} \sum_{k=t-W}^{t} x_i(k)$$

In this case, xi(t) refers to the measurement of the ith body function at time t, while W represents the length of the time window under consideration. The following is how we find the standard deviation of the signal within the window:

$$\sigma_i(t) = \sqrt{\frac{1}{W} \sum_{k=t-W}^{t} (x_i(k) - \mu_i(t))^2}$$

These numbers are constantly updated by the system as new information is received, keeping it in rhythm with any changes in the patient's condition. After we have established the statistics, the system then establishes levels of alarm that are adjusted according to each patient's normal levels. We then decide what the proper level of each statistic is by comparing how much it varies from the average we have been observing. "The line we use to decide something is ..."

$$T_i(t) = \mu_i(t) + \lambda \sigma_i(t)$$

In this case, λ simply represents a number that defines how far the threshold can vary from the original position. It can also accommodate changes in the natural variations in the patient's body. After establishing the adaptive thresholds, it then determines how far each measurement varies from its normal state.
Using this information, we can then establish a total risk score that defines the health of the patient. In essence, instead of focusing on individual settings, the algorithm will

use all the deviations from the normal state across different parameters. It can do this in a more holistic manner because it considers how different systems in the body work in unison. To do this, it simply calculates the total risk score by compiling all the information.

$$R(t) = \sum_{i=1}^{n} w_i D_i(t)$$

In this case, Di(t) indicates the amount by which parameter 'i' has changed, while wi represents the weighting factor for each physiological parameter. The weighting factors show the significance of each parameter in a clinical environment. After calculating the risk score, the system checks if it is too risky according to our threshold. If the risk score is still low, it just keeps track of your body signals without sending any alarm.

If the risk score increases beyond our threshold, it checks again and asks you to confirm something. It takes some time after detecting something unusual in your body signals to ensure it is not a false alarm. It only sends an alarm if it is actually unusual. If unusual activities continue for some time, an alarm pops up on the doctor's screen.

This alarm shows the medical staff what is wrong with your body signals and how risky it is. After sending the alarm, it keeps track of your body signals, updating normal levels for each patient and considering multiple risk factors. The algorithm works very fast, making it suitable for real-time applications, such as ICUs. It keeps updating normal levels for each patient while considering multiple risk factors, reducing false alarms while detecting changes in a patient's condition.

Results and Analysis

We wanted to test how good our new method of making the alarm better and more personalized would be. For this, we used data related to patients in intensive care, and this is the data that is usually used for this sort of study. Usually, the data has continuous information about things like heart rates, breathing rates, blood pressure, and oxygen levels, and so on, of patients in the ICU. What we wanted to test was how good our new monitoring system would be at reducing the number of false alarms. But at the same time, we wanted to test if the monitoring system would still be able to pick up serious health issues correctly. We compared our adaptive threshold monitoring system with the traditional static threshold monitoring methods to test our hypothesis. In traditional monitoring systems, the alarm goes off if the patient's parameters go beyond a certain level. Even though this method is used in most hospitals, the alarm can go off due to various reasons or due to normal values in the patient's parameters. But in our proposed method, the alarm levels change automatically.
They change by looking at the continuous parameters and using stats to determine things. They can look at several things at one time and combine them into one risk score. Before we went ahead with our statistical modeling, we had to clean up the signals to get rid of noise and abnormal values. We had to determine the normal health state of the patient by looking at their parameters. We used techniques like moving averages and standard deviation to get a good idea.

We developed thresholds based on how much things varied statistically. So, if the blood pressure or heart rate started to change from a person's normal range, it mashed all those changes together and produced a single overall risk score. The alarm then checked whether that single risk score stayed above a chosen level for a given length of time using a 'confirmation window.'

In order to judge how well our system works, we used a variety of metrics, such as accuracy, sensitivity, specificity, and the rate of false positives. Accuracy tells us how often the alarm predictions were right. The sensitivity tells us how good the system is at detecting real abnormal events. The rate of false positives tells us how good it is at detecting normal events.

Our tests have revealed that this adaptive system, which adjusts itself, really works, and it works much better than the older systems, which used fixed limits, by a wide margin.

The new system was more accurate and precise in its targets, yet it gathered all the information that was required. It also gave fewer false alarms, owing to its patient-specific baseline model and its confirmation window.

This method is not only applicable to large-scale issues but also to small-scale changes in the body that are not necessarily issues. Table 1 provides a comparison between the conventional method of monitoring and our adaptive monitoring system to determine how well they compare. The results show that the new system increases the reliability of alarms and decreases the number of false alarms. It is not as sensitive as the fixed-limit system but still improves the usefulness of the system by decreasing unnecessary alarms. This means that the system provides fewer unnecessary warnings, allowing caregivers to focus on patients who require immediate attention.

Metric	Static Threshold System	Proposed Adaptive System
Accuracy	84%	91%
Sensitivity	91%	89%
Specificity	70%	86%
False Positive Rate	30%	14%

The experiments conducted also demonstrate that the system performs best when it considers several risk factors simultaneously. By examining several risk factors simultaneously, the system identifies issues that could be overlooked if each factor is considered individually. This makes the system more reliable and less prone to overlooking significant changes in a patient's condition. The experiments conducted demonstrate that the new alarm system is effective in alleviating alarm fatigue among ICU

personnel. The system appears to be reliable in real-time applications and strikes a balance between accuracy and practicality for real-time medical applications.

Conclusion

In today's hospitals, especially in the ICU, we rely on constant monitoring systems to keep tabs on our critically ill patients, ensuring they are safe and getting the best care. This technology is excellent in picking up abnormal bodily signals, but the number of false alarms from conventional monitors has become a nuisance. Most alarm systems use one standard setting that does not take into account how each individual's body can be different. This has resulted in an overwhelming number of alarms that are not really significant, which has worn out the staff. When alarm after alarm goes off, people start to tune out or ignore them, which can be serious.

This paper will explain a smarter approach to hospital alarm systems, especially designed for patients in the ICU. Previous alarm systems used only one level of alarm, which was supposed to be universal for all patients. This, however, was not really effective. Our alarm system, however, will be smarter. This alarm system will learn each patient's normal patterns and adjust the alarm settings accordingly.

In addition to that, our alarm system will also blend the risk of different vital signs, analyzing how they change in relation to each other. This will give us a more complete picture of our patients' conditions. We have also added a confirmation window to our alarm system to make sure that the alarm will only go off when abnormal conditions persist, not just for a quick second. This will also eliminate those minor signal blips, especially in the ICU.

The alarm system will use both hardware and software to pick up the signal, analyze it, and then determine whether or not to send out an alarm.

The system works well enough to be incorporated into medical devices, and we tested it. The adaptive monitoring reduced false alarms significantly compared to traditional systems based on fixed thresholds. It was more specific and accurate, yet still responsive to significant health events. It helps to concentrate the attention of doctors and nurses on patients who actually require immediate attention, and it also makes the whole process of monitoring more reliable. Thus, the adaptive alarm optimization framework we talked about is a good one – a usable, applicable solution for more effective alarm management in ICUs that can be applied at the moment and even developed further if necessary.

In conclusion, this system makes patient care safer by reducing the number of annoying alarms and by enhancing the performance of the monitoring equipment. Looking into the future, we might introduce more sophisticated machine learning to enhance predictions, introduce additional physiological variables, and test the whole system against a larger body of real-world data to make sure it acts as it should.

Future Work

Although this new alarm system for ICUs shows great promise in reducing the number of false alarms, it is still possible to take it a step further and study it more in-depth. Currently, the system relies heavily on statistics to identify special thresholds and track the vital statistics of each patient. This makes it very effective since it can be implemented right away.

However, if we add some form of smarter data analysis, it is possible to make it an even more effective tool for anticipating patient complications. Perhaps we can look into using machine learning and artificial intelligence to identify early signs that a patient is experiencing complications. By using machine learning, we can look into using logistic regression, decision trees, and neural networks to identify connections between various body measurements. This, in turn, can be used to forecast possible complications before they become major issues.

In the future, it is possible to take it a step further by incorporating additional information into the system used for patient monitoring. Currently, the patient monitoring systems used in ICUs only track a few basic pieces of information. If we were to add information such as ECG, patient movement, lab results, and electronic patient records, it is possible to get a much more accurate picture of the patient’s condition. This, in turn, can be used to identify whether the patient is experiencing complications or not.

In addition, it is possible to take it a step further by making it a much more versatile tool, such that it can be used across multiple hospital networks. Currently, most hospitals have multiple information systems and monitoring systems running at the same time. This means that it is possible to take it a step further by making it compatible with the information systems used in hospitals.

We should also conduct large-scale experiments with actual patients. Although our method has been shown to work with public data, actual patients may have different challenges, such as different sensor types, patient movement, and the rhythms of a hospital. Actual experiments in hospitals can help us understand how our method can actually work and even tweak our algorithm to fit the needs of actual doctors.

Next, we should investigate the possibility of developing smart tools for doctors and decision support tools to improve adaptive monitoring. For instance, if monitoring tools can be made easier to understand, doctors may use them more. Indeed, if they can understand the rationale behind the alarm, they may even trust our method more.

Future work in these directions may help us improve adaptive ICU monitoring even more and develop healthcare technology that is not only smarter and more reliable but patient-centered.

Abstract*— This project abstract implies that high security areas , very important base security areas and other government confidential infrastructure require cutting edge surveillance technology . Usually in large, complex environments and vast buildings , traditional approaches such as wall mounted CCTV and manual monitoring was mainly implemented . These often result in limited coverage and slower response , sometimes in critical cases, loss of life occurs. This indicates the need for a highly flexible security system with automated detection and monitoring capabilities of threats in real life . (ADIDAS - D) Autonomous Defence Intruder Detection Aerial System - Drone is an Artificial intelligence ML based security and surveillance drone designed for detecting the intruders and unauthorised person in highly secured zones . The proposed system integrates an autonomous drone with advanced microprocessor-installed machine learning algorithm and other intelligent techniques to improve the performance of the drone .The drone also integrated with a camera . From the Camera the live feed will be continuously fed to the microprocessor and with the help of machine learning models , the drone detects the human presence and identify the intruders in the monitored area . The Key role of the drone is once it spots an individual as an intruder , then it will undergo the further security processes to confirm whether the person is authorised or an unauthorised person . As the aerial system is combined with the AI-driven visual detection , the drone can monitor wider areas comparing to the traditional CCTV systems and this will be a more efficient system . The ADIDAS -D system enhances situational awareness by using real-time monitoring and quick identification of potential security threats . This system's aerial coverage capability allows efficient surveillance in inaccessible environments while maintaining continuous surveillance .The integration of Artificial intelligence and machine learning improves the accuracy and reliability while reducing the threats and false detections . Overall , the proposed system provides the best scalable solution for modern surveillance applications . This contributes to improved safety , faster response and better protection .

Keywords- Autonomous Intruder Detection, Artificial Intelligence, Machine Learning, Defence Surveillance.

I. INTRODUCTION

The security of restricted and sensitive areas such as VIP houses, weapon good down and R&D bases requires modern surveillance systems . The traditional monitoring system focuses only on fixed surveillance cameras, perimeter security systems and manual monitoring . With these approaches, basic security coverage is achieved . But they often suffer from limitations such as restricted field of view , blind spots and delayed response in large environments . As a result , recognising and preventing assassins and intruders are really remains a challenging task. The integration and advancements of Artificial Intelligence with machine learning models and UAV (unmanned aerial system) improve the security surveillance . This leads the drone to perform intelligent visual analysis , human detection , threat detection and enables it to take required action at that instant during surveillance operations .

Using the machine learning , the models can be trained to differentiate the authorised persons and intruders within the circumstances. By combining the aerial system with onboard visual system ,it becomes possible to create a system that is responsive and adaptive to a dynamic environment . To address these challenges , this paper presents ADIDAS-D (Autonomous Defence Intruder Detection Aerial System – Drone), an intelligent drone designed to detect and monitor unauthorized intruders in highsecurity zones.

The proposed ADIDAS-D system aims to provide a better solution for modern surveillance applications where rapid detection and monitoring of intrusions are critical.

II. RELATED WORK

In traditional system of security , the cameras where mostly fixed to the wall and human were involved for the security task leads to more limitations in security and delayed response time . Therefore , using aerial system for surveillance will help to overcome these limitations as per the researchers and confessed that integrating on board Artificial intelligence techniques will increase the robustness to the aerial system Research has currently focused on four primary methods of conducting surveillance.

- Wall mounted CCTV for continuous monitoring
- Drone / aerial System monitoring (large area coverage).
- Human Detection / recognition (AI/ML model).

- Autonomous identification through computer vision

The Continuous analysis by researchers helped to unlock an seamless technology to the users by integrating all lively technology such as drones , computer vision , Artificial intelligence capabilities and Machine learning .

III. Proposed Method

A. System Overview

ADIDAS–D will operate as an autonomous aerial surveillance drone that has onboard visual sensors and intelligent intrusion detection capabilities. The drone will continuously capture visual data of the surveillance area and utilize AI-based visual recognition algorithms to process the data in real-time. the drone enables wider coverage compared to traditional ground-based surveillance systems. The ADIDAS-D system has the following primary objectives:

- Continuous surveillance of the restricted area
- Detect the presence of human beings in the area being monitored
- Identify suspected persons
- Increases situational awareness

B. Hardware Components

The proposed drone integrates several hardware modules that are required for autonomous visual monitoring and lethal agent spraying .

- Camera Module – to captures live video for visual analysis
- Embedded Processing Unit (Jetson Nano) – to performs onboard AI processing
- Arduino UNO – Radio Frequency ID integration

These hardware combination ensures continuous data acquisition during surveillance operations .

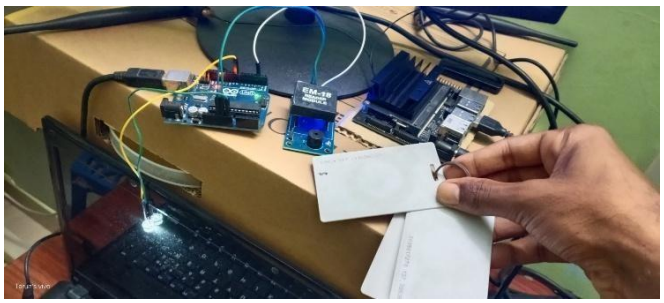

Fig. 1. **Radio Frequency ID Check**

C. AI-Based Intruder Detection

To enable intelligent monitoring, the system integrates intelligence based computer vision models for detecting intruder and unauthorised person within the monitored zone .The onboard camera continuously captures video frames which are processed by using machine learning algorithms.

The detection module performs the following tasks:

- Capture live video frames from the drone camera
- Process the video frames using computer vision techniques
- Detect intruder using trained machine learning models in surveillance region .

By analysing the visual data in real time, the drone can automatically identify suspicious person without relying entirely on human monitoring.

D. Surveillance Workflow

The Surveillance workflow of the ADIDAS-D system follows a structured pipeline. Each stage of the pipeline contributes to identifying and monitoring the potential intruders .

The Surveillance workflow includes:

- Drone Deployment – The drone is deployed to patrol in designated area.
- Video Acquisition – The onboard camera continuously captures the surrounding environment.
- Frame Processing – Video frames are processed by the onboard computing unit.Here, Jetson Nano is used .
- Human Detection – Machine learning models analyze frames to detect presence of humans.
- Intruder Identification – Detected individuals are evaluated to determine threats.
- Monitoring and Response – The system continues surveillance, provides alerts and sprays non-lethal agent .
- This workflow allows the drone to detect intrusions in real time autonomously .

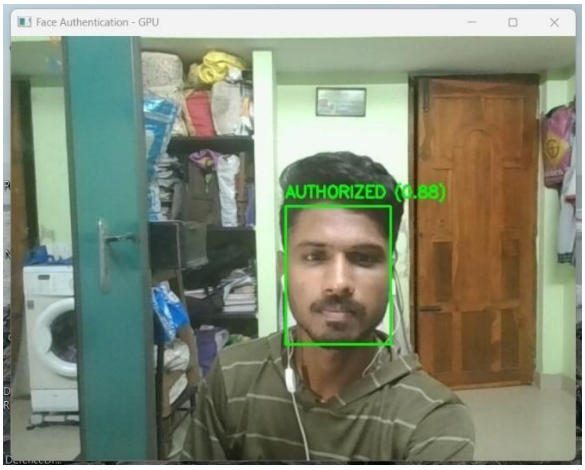

Fig. 2. **Face Check**

E. Advantages of the Proposed System

The proposed ADIDAS-D system offers several advantages compared to the traditional surveillance approaches.

Key benefits include:

- Wider surveillance coverage
- Real-time intruder detection using AI-based vision models
- Reduced dependence on manual monitoring
- Improved situational awareness than traditional systems
- Easy deployment in large areas
- The above-listed advantages make the setup suitable for defence surveillance and other confidential infrastructure

IV. SYSTEM ARCHITECTURE

The system architecture of ADIDAS-D (Autonomous Defence Intruder Detection Aerial System – Drone) includes autonomous drone, advanced microprocessor or single-board computer with Camera integrated , microcontroller like Arduino to install RFID scanners , Non-lethal agent sprayer and intelligent machine learning models for intruder detection.

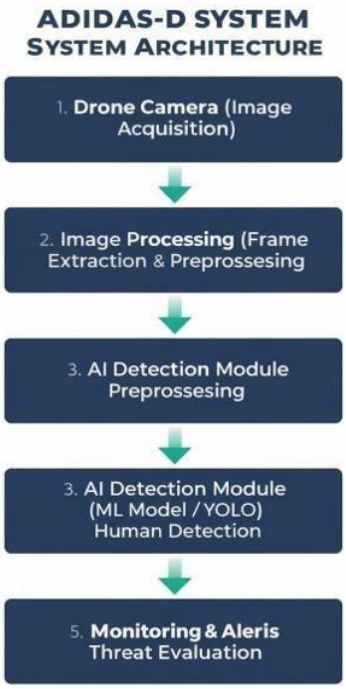

Fig. 3. Illustrates the design architecture of the ADIDAS-D system.

This ML models enable real-time intruder detection . The architecture is designed in such a way as to combine drone mobility, onboard sensing, and machine learning for efficient monitoring .The overall architecture consists of multiple intelligent machine learning modules that work together to perform surveillance, detection, and to perform reactions .

A. Image Acquisition Module .

The very first step of the surveillance process starts with the image acquisition module . The camera installed on the microcontroller or single board computer will continuously capture the live video of the surveillance zone during the flight operation. The captured visual is considered as data input for the intelligent machine learning models . The captured data will be analysed by the machine learning module . As this security system is installed in the drone, vast observation of surveillance zone can be achieved . This minimizes the intruder actions in the security zones .

Main functions are:

- Continuous capture of real-time video frames
- Monitoring of the designated surveillance area
- Providing input data for the detection system

B. Data Processing Module

The captured video frames from the surveillance region are transmitted to the onboard processing unit for the task of analysis. The embedded platform performs frame preprocessing.

It also prepares the data for artificial intelligence-based detection.

The data preprocessing operations include:

- Frame extraction from video streams
- Image resizing and normalization
- Preparation of frames for machine learning models

These preprocessing steps improve the efficiency of the detection process.

C. AI-Based Detection Module

The AI-based detection is responsible for identifying the presence of intruder or unauthorised persons within the monitored environment. Machine learning based computer vision algorithm analyze the incoming video frames to detect .

The module performs:

- Human detection using trained vision models
- Identification of potential intruders
- Continuous monitoring of detected objects

By using machine learning techniques, the system can automatically identify individuals present in the area.

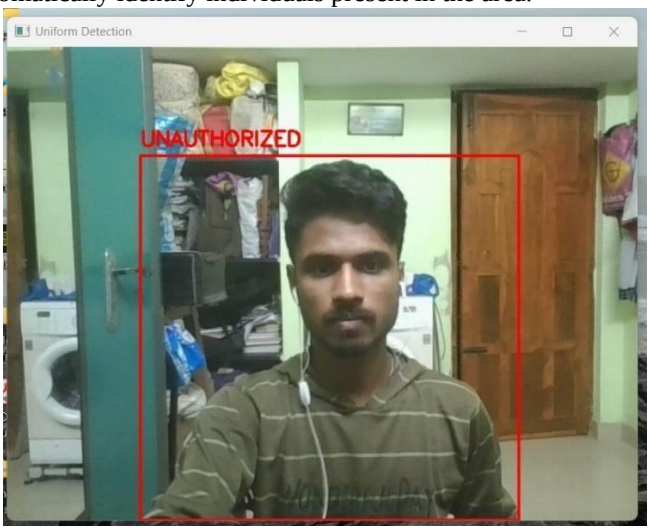

Fig. 4. **Uniform Detection**

D. Decision and Monitoring Module:

Once a person is detected, the system evaluates the detected person information and determines whether the person is authorised or unauthorised person. The monitoring module maintains continuous observation of detected individuals within the surveillance region.

The key functions are :

- It will be monitoring the detected individuals
- Then tracking movement within the surveillance zone
- Generating alerts or notifications when needed

Due to the presence of this module the ADIDAS-D improves the situational awareness and assists security regarding to the potential threats.

E. Surveillance Output Module

The end stage of the system architecture involves presenting the processed information of the intruder for security response. The results of the process can be used to trigger alerts or provide real-time surveillance feedback that will be useful for further investigation purposes .

The output module gives:

- Real-time monitoring information
- Intrusion alerts when suspicious activity is detected
- Continuous surveillance updates

V. Experimental Evaluation

A. Evaluation Metrics

To assess the performance of the ADIDAS-D, several standard evaluation metrics used for intelligent machine learning techniques . Because false alerts may lead to the big chaos, energy and capital loss . At the end the confidence that humans have on the system may reduce. So the evaluation was done in such a way to increase the accuracy .

The evaluation metrics are:

- Detection Accuracy – measures the overall correctness and here it is above 8.5.
- Precision – indicates how many detected objects are the correct detections. The precision is set to 93% to avoid false detection .
- Recall – It is how effectively the system detects all possible humans .
- Processing Time – evaluates the speed of detection during real-time monitoring.

These metrics help in analysing the accuracy and the efficiency of the proposed surveillance system.

B. Experimental Setup

The experimental setup was done to test the performance of the ADIDAS-D system under surveillance conditions. The drone was equipped with a camera and a single-board computer unit, capable of running machine learning models for visual detectionThe main components used during the experiment are:

- Drone Platform – basic quad configuration for aerial monitoring.
- Embedded Processing Unit – Jetson Nano for onboard AI processing
- Camera Module – used for capturing live surveillance footage
- Machine Learning Model – custom trained models used for intruder detection

The system captures video frames during flight and processes the feed in real-time to detect intruder presence in the monitored zone.

C. Test Environment

The ADIDAS-D was tested in a zone that simulates a restricted area monitoring. During the experiment, the system continuously captured visual data for intruder detection while flying over the surveillance region.

The test environment includes:

- Open surveillance areas
- Controlled monitoring zones
- Presence of potential intruders

The drone monitored the area while the intelligent machine learning models analyzed incoming camera feed to detect intruder presence.

D. Performance Observation

The overall results demonstrate that proposed ADIDAS-D system can successfully detect the intruders presence in real time using AI ML based vision models. The aerial monitoring allows the system to cover vast areas compared to traditional stationary surveillance systems. And the immediate reaction of spraying non-lethal agent reduces the percentage of damage going to happen .

Key observations from the experiment are:

- Effective detection in the surveillance region
- Continuous monitoring capability
- Improved situational awareness
- Reliable detection performance during real-time processing

These results indicate that the proposed system can support security monitoring applications where rapid detection of unauthorized individuals is required.

VI. RESULTS

The experimental results demonstrate the effectiveness of our solution ADIDAS-D (Autonomous Defence Intruder Detection Aerial System – Drone) in detecting intruder presence or assassins presence and using aerial surveillance in restricted areas. The system was tested under controlled conditions where the drone captured real-time video and processed it using machine learning-based models.During the experiment, the drone continuously monitored the surveillance region and mean while the single board computer was fed with video feed from the camera and analysed the incoming video. The Intelligent machine learning based detection model successfully identified intruders presence in the surveillance zone, proving the capability of the system.

- The key observations from the experimental evaluation are:
- The system successfully detected intruders in the surveillance area.
- Real-time processing was achieved using onboard AI computation.
- Aerial monitoring allowed wider surveillance coverage compared to stationary cameras.
- The detection system demonstrated stable performance during continuous monitoring.

Detection Performance of ADIDAS-D System

S.NO	Metric	Value
1	Detection Accuracy	93%
2	Precision	91%
3	Recall	92%
4	Average Processing Time	~45 ms per frame

Table .1. presents the detection performance of the ADIDAS-D system.

The results indicate that the ADIDAS-D can effectively detect unauthorised persons in real-time meanwhile maintaining reliable performance during aerial surveillance. The integration of drone mobility with machine learning-based detection improves the capability and situational awareness of ADIDAS-D. Overall, the ADIDAS-D system demonstrates the feasibility of using autonomous UAV System combined with machine learning intelligence systems for intruder detection and surveillance in restricted areas.

VII. DISCUSSION

The experimental results demonstrate that the proposed ADIDAS-D (Autonomous Defence Intruder Detection Aerial System – Drone) provides an effective approach for aerial surveillance and intruder detection comparing to the traditional system. By integrating the drone with artificial intelligence and machine learning, the system is capable of monitoring larger areas and detecting intruder presence in realtime. This combination of cutting-edge technology allows

the surveillance system to operate more dynamically compared to traditional fixed camera systems.

One of the key strengths of the ADIDAS-D is its ability to perform real-time visual analysis during aerial surveillance. The integration of single-board computer enables the drone to analyse captured video without relying on external infrastructure, which improves response speed and operational flexibility. Additionally, aerial monitoring provides better visibility and wider coverage, reducing the limitations associated with wall-mounted surveillance systems.

The study also highlights several practical advantages:

- Improved surveillance through aerial monitoring.
- Real-time intruder detection using ML-based techniques.
- It reduces dependence on manual monitoring.
- It Enhanced the situational awareness in large environments.

Despite of these advantages, some limitations are there.These limitations are because of the Environmental conditions such as low lighting, weather disturbances, and other factors may affect the performance. Also,the operational duration is dependent upon the battery capacity, which can limit longterm continuous surveillance.

Future improvements on:

- Enhancing accuracy using advanced deep learning models.
- Integrating multiple drones for cooperative surveillance.
- Improving flight endurance for extended monitoring.

Overall, the proposed ADIDAS-D system demonstrates the potential of combining autonomous aerial system with intelligent machine learning techniques enhance the security monitoring in surveillance and modern applications.

.

VIII. CONCLUSION

ADIDAS-D (Autonomous Defence Intruder Detection Aerial System – Drone) is an intelligent aerial surveillance system designed to improve the security in restricted areas and highly confidential environments. The proposed system integrates an autonomous UAV with artificial intelligence and machine learning-based techniques to detect intruder or assassins in realtime. By combining UAV with visual intelligence analysis, the system enables continuous monitoring of large areas that are difficult to supervise using traditional surveillance systems. The experimental evaluation demonstrates the proposed system can effectively detect human presence and provide real-time monitoring during aerial surveillance. The integration of singleboard computer allows the UAV to analyse the camera feed and assist in identifying unauthorized individuals . This helps to improves situational awareness and enables faster response to the security threats.

The ADIDAS-D highlights the potential of integrating autonomous UAV with the AI-driven detection systems for modern surveillance applications. With further improvements in detection models, flight endurance, and multi-drone (swarm) coordination, the system can be extended to support more advanced security operations. Totally , ADIDAS-D provides a scalable solution for intelligent intruder detection and aerial security.

Abstract*—Electric vehicles are environmentally friendly but face challenges such as limited charging infrastructure and long charging times, since traditional wired charging requires vehicles to remain stationary. This paper presents a prototype of wireless EV charging while moving using inductive power transfer between a transmitter coil embedded in the road and a receiver coil in the vehicle. An Arduino Uno controls the system, monitors charging voltage through a voltage sensor, and displays it on a 16×2 LCD using an I2C interface, while a Bluetooth module enables remote control via a smartphone. The prototype demonstrates that dynamic wireless charging can reduce dependence on charging stations and support future smart transportation systems.

Keywords*—Wireless Charging, Electric Vehicles, Inductive Power Transfer, Arduino UNO, Smart Roads.

I. INTRODUCTION

Electric vehicles are gaining popularity across the world due to increasing environmental concerns and the need to reduce dependence on fossil fuels. Conventional vehicles powered by petrol and diesel engines produce harmful emissions that contribute to air pollution and global warming. Electric vehicles provide a cleaner and more sustainable alternative for transportation.

Despite these advantages, the adoption of electric vehicles still faces several challenges. One of the main problems is the limited charging infrastructure available for EV users. Charging an electric vehicle using conventional wired chargers can take several hours, especially when using standard home charging systems. This creates inconvenience for drivers who need quick and continuous transportation.

Wireless power transfer technology offers a promising solution to this problem. By transferring electrical energy through electromagnetic induction, power can be delivered without direct electrical contact between the source and the vehicle. This eliminates the need for cables and connectors while also improving safety and convenience.

Dynamic wireless charging is an advanced concept where vehicles receive power while moving along specially designed charging roads. In this concept, transmitter coils are embedded under the road surface while receiver coils are installed under the vehicle. As the vehicle moves over the coils, electrical energy is transferred wirelessly and used to charge the battery.

The main objective of this paper is to design and implement a small-scale prototype that demonstrates wireless EV charging while the vehicle is moving. The system integrates wireless power transfer, voltage monitoring, and Bluetooth-based vehicle control using an Arduino microcontroller platform which is explained in proposed system.

II. LITERATURE SURVEY

Wireless power transfer technology has attracted significant attention in recent years as an effective solution for charging electric vehicles without the need for physical connectors. Many researchers have focused on inductive power transfer systems to make EV charging more convenient and to reduce reliance on traditional wired charging infrastructure. For example, Li and Li presented a detailed study on wireless power transfer for electric vehicle applications and highlighted the advantages of inductive charging systems in modern transportation [1].

Several studies have also examined the design and performance of inductive power transfer

systems used in EV charging. Zhang et al. analyzed various coil configurations and system parameters in order to improve the efficiency of wireless charging systems for electric vehicles [2]. In a similar study, Feng et al. developed a wireless charging system based on resonant inductive coupling, which demonstrated improved energy transfer efficiency between the transmitting and receiving coils [3].

Another important area of research is dynamic wireless charging, where electric vehicles can receive energy while moving on specially designed charging roads. Li et al. proposed a dynamic wireless charging system using inductive power transfer that allows continuous energy transfer to vehicles during motion [4]. Likewise, Ahmad et al. introduced a high-efficiency wireless power transfer system specifically designed for electric vehicle charging applications [5].

The development of wireless charging infrastructure has also been widely explored. Zhang et al. designed a dynamic inductive charging infrastructure that uses coils embedded in the road, enabling electric vehicles to charge while traveling on highways [6]. In addition, Li et al. investigated coil optimization techniques to further enhance the efficiency and performance of wireless charging systems [7].

Many researchers have also reviewed recent advancements in wireless charging technologies. Kumar et al. provided a comprehensive review of wireless charging techniques for electric vehicles, discussing different power transfer methods and their practical applications [8]. Similarly, Chen et al. demonstrated a dynamic wireless charging system capable of transferring energy to moving electric vehicles through inductive coupling methods [9].

Recent work has also focused on prototype development and performance evaluation. Islam et al. designed and implemented an inductive wireless charging system for electric vehicles and evaluated its charging performance [10]. Liu et al. further analyzed the efficiency and operational characteristics of wireless power transfer systems used in EV charging applications [11].

In addition, Patel and Shah proposed the concept of wireless charging road infrastructure to support continuous charging of electric vehicles during travel [12]. Gupta et al. introduced the idea of smart wireless charging infrastructure for urban transportation systems [13]. Wang et al. investigated high-power dynamic wireless charging systems designed for real-world EV applications [14]. Finally, Singh et al. discussed future trends and emerging technologies in dynamic wireless charging systems that could support the large-scale adoption of electric vehicles in smart transportation networks [15].

.

III. PROPOSED SYSTEM

The proposed system is a prototype model designed to demonstrate wireless electric vehicle charging while the vehicle is moving. The system consists of three major subsystems: wireless power transfer, vehicle control system, and monitoring system.

The wireless charging subsystem consists of a transmitter coil placed on the charging track and a receiver coil mounted under the vehicle chassis. When alternating current flows through the transmitter coil, it generates a magnetic field. This magnetic field induces voltage in the receiver coil through electromagnetic induction.

The control subsystem is built using an Arduino Uno microcontroller. The Arduino receives input from the voltage sensor module and processes the measured voltage values. These values are then displayed on a 16×2 LCD display through the I2C communication interface.

The vehicle motion subsystem includes four DC motors connected to an L298N motor driver module. The motor driver allows the Arduino to control the speed and direction of the motors. An HC-05 Bluetooth module enables wireless communication between the Arduino and a smartphone application, allowing the user to control the vehicle remotely.

A. Hardware Components

The major hardware components used in the system includes Arduino Uno microcontroller, L298N motor driver, wireless transmitter and receiver coils, HC-05 Bluetooth module, voltage sensor module, LCD display with I2C interface, DC motors, battery, and LED indicators as shown in Table 1 and Table 2..

TABLE I. HARDWARE DEVICES USED IN THE PROPOSED SYSTEM

Component	Specification	Quantity	Purpose
Arduino UNO R3	ATmega328P, 16MHz, 5V	1	Main microcontroller
HC-05 Bluetooth	v2.0+EDR, 9600 baud	1	Wireless BT control
L298N Motor Driver	35V, 2A per channel	1	Dual H-bridge control
DC Gear Motor	6V, 200 RPM	4	4-wheel drive
Wireless Charger TX	5V/1A, 100-205 kHz	1	Ground charging station
Wireless Charger RX	5V/1A output	1	Vehicle charging receiver
Voltage Sensor Module	0-25V input, 0-5V output	1	Charging voltage monitor
LCD 16x2 with I2C	HD44780, PCF8574, 0x27	1	Voltage display
LED (Green/Red)	5mm, 20mA	2	Charging status indicator
Resistor 220Ω	1/4W Carbon Film	2	LED current limiting
Chassis (4WD Car)	Acrylic/ABS, 200×170mm	1	Vehicle body
Li-Ion Battery	7.4V, 2000mAh	1	Power supply for system
Jumper Wires	Male-Male, Male-Female	40	Prototyping connections
Breadboard	830 tie-point	1	Circuit prototyping
USB Cable (Type-B)	For Arduino programming	1	Code upload

TABLE 2.SOFTWARE USED IN THE PROPOSED SYSTEM

Software / Tool	Version	Purpose
Arduino IDE	2.x / 1.8.x	Firmware development & upload for Arduino UNO
LiquidCrystal_I2C Library	1.1.2	I2C LCD control (Frank de Bruijn)
Wire Library	Built-in	I2C communication protocol stack
SoftwareSerial Library	Built-in	Bluetooth UART communication
Bluetooth Serial App	Android 5.0+	Sends control commands via BT to HC-05
Proteus 8 Professional	8.15+	Circuit simulation and schematic design
Fritzing	0.9.x	PCB layout and breadboard diagram design
VS Code + Arduino Ext.	Latest	Advanced code editing environment

The Arduino Uno serves as the central controller that coordinates all system operations. The motor driver controls the movement of the vehicle, while the Bluetooth module receives commands from a smartphone application. The voltage sensor measures the output voltage from the wireless receiver circuit and sends analog signals to the Arduino for processing.

B. Working Principle

The working principle of the wireless charging system as shown in Fig 1 is based on electromagnetic induction. When an alternating current flows through the transmitter coil, it produces a time-varying magnetic field around it. When the receiver coil enters this magnetic field, an electromotive force is induced across the coil terminals.

The induced voltage is then rectified using a diode rectifier circuit to produce a DC voltage. This DC voltage is used to charge the battery of the electric vehicle. The voltage sensor module measures the output voltage and sends the data to the Arduino microcontroller.

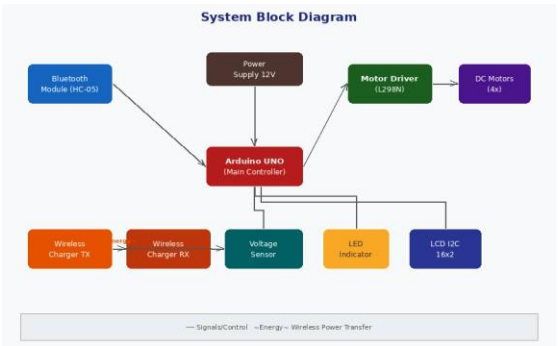

Fig 1. Workflow of the proposed system

The Arduino processes the voltage values and displays them on the LCD screen. When sufficient charging voltage is detected, an LED indicator lights up to show that charging is taking place. Meanwhile, the Bluetooth module allows the user to control the movement of the vehicle using commands sent from a smartphone application.

IV. EXPERIMENT AND RESULT

A prototype model of the wireless EV charging system was built using the hardware components described as shown in Fig 2. The transmitter coil was placed on a charging track while the receiver coil was mounted underneath the vehicle chassis.

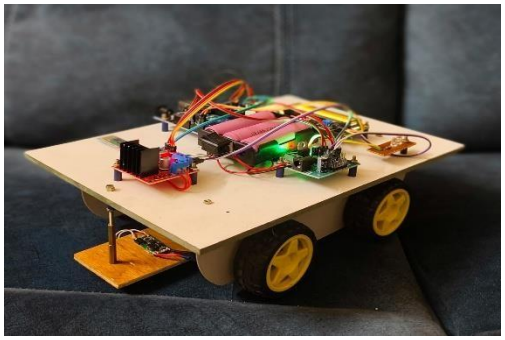

Fig 2. Hardware implementation of proposed system

During testing, the transmitter module generated a magnetic field that induced voltage in the receiver coil when the vehicle moved over the charging track. The voltage sensor successfully detected the charging voltage and transmitted the data to the Arduino microcontroller.

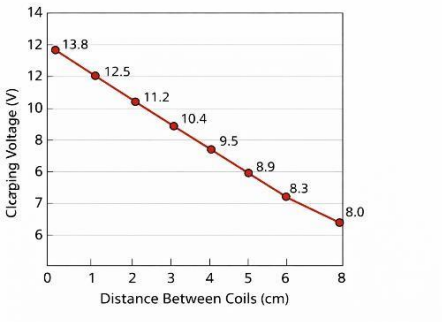

Fig 3. Charging Voltage vs Distance graph

Fig 4 shows that LCD display showed the voltage values in real time, allowing users to monitor the charging process. Fig 5 shows that LED indicator turned on whenever charging voltage was detected, confirming successful wireless energy transfer.

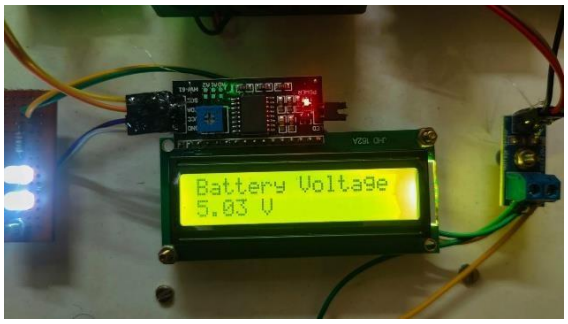

Fig 4. Amount of voltage charged

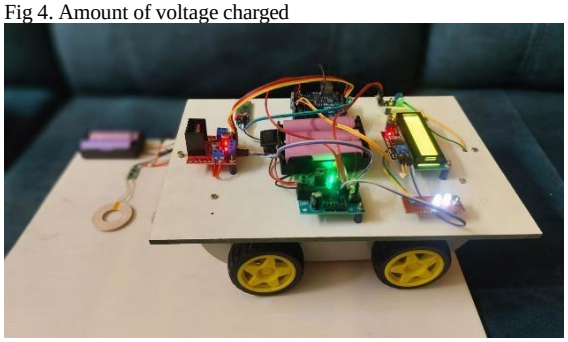

Fig 5. Real-time testing of proposed system

The Bluetooth module enabled the vehicle to move forward, backward, left, and right based on commands received from a smartphone. The response time between command transmission and vehicle movement was very small, demonstrating reliable wireless communication.

V. ADVANTAGES AND APPLICATIONS

The proposed wireless EV charging system offers several advantages compared to traditional wired charging systems. It eliminates the need for physical connectors and cables, reducing wear and maintenance issues. The system also improves user convenience because vehicles can receive power without stopping for charging.

Wireless charging technology can be applied in smart highways, electric buses, autonomous vehicles, and robotic transportation systems. Dynamic wireless charging roads could significantly increase the driving range of electric vehicles and reduce the need for large battery packs.

VI CONCLUSION

This paper presented the design and implementation of a wireless electric vehicle charging prototype using inductive power transfer technology. The system integrates wireless power transfer, Bluetooth-based vehicle control, and real-time voltage monitoring using an Arduino microcontroller. The transmitter coil placed on the road transfers electrical energy to the receiver coil mounted on the vehicle through magnetic coupling, enabling wireless charging without physical connectors.

The experimental results demonstrate that wireless charging technology can successfully transfer energy to a moving vehicle prototype. The developed model proves that inductive power transfer can be effectively used for dynamic charging systems and can reduce the need for frequent stationary charging of electric vehicles. This approach can contribute to improving the practicality and convenience of electric vehicle usage.

*Future Scope***:** In the future, the proposed system can be further improved by increasing the power transfer efficiency and transmission distance between the coils. Advanced power electronics circuits and optimized coil designs can be used to enhance the charging performance. The system can also be extended to support higher power levels suitable for real electric vehicles and integrated with smart road infrastructure. Additionally, large-scale implementation of dynamic wireless charging roads can help reduce battery size requirements and enable continuous charging for electric vehicles during travel.

Abstract*—This paper proposes SmartQCare, a smart queue management system designed to streamline patient flow in small and medium clinics through automated registration and waitlist management. The planned system would allow patients to book consultation tokens and track real-time queue positions via a web/mobile app, while clinic staff monitor flow via a secure dashboard, potentially reducing delays. An AI-powered chatbot (targeting both platforms) is designed to handle FAQs (e.g., registration, queue status), alongside a configurable token assignment system supporting both FIFO and priority-based methods (the latter dynamically weighting age, condition severity, and wait time). The system will be developed using Firebase Realtime Database (backend), HTML/CSS/JavaScript (web), and Flutter (mobile), with cross-platform accessibility as a key goal. Theoretical models suggest improvements over traditional queue systems in transparency and efficiency

Keywords*—healthcare automation, smart queue system, real-time scheduling, ai chatbot, firebase, token priority algorithm

I. INTRODUCTION

Queue management is a must-have when it comes to determining the functional efficiency of clinics and overall patient satisfaction. Most clinics still use traditional token-based patient flow management, which unfortunately results in long waiting times, a lack of transparency in the process, and growing patient dissatisfaction. With outpatient volumes increasing unabated, urban and semi-urban areas are not exempt from this trend, hence the need for innovative, smart, real-time and cross-platform queue management solutions that can address these issues is more pressing than ever.

SmartQCare meets these requirements perfectly through a very smart web and mobile-enabled queuing system powered by Firebase as its underlying platform. Patients can book their tokens easily, monitor live queues in real-time, and get instant assistance through an interactive chatbot. Unlike most systems in the market, SmartQCare has an optional priority-based algorithm that manages tokens intelligently during peak hours when demand is highest.

II. LITERATURE REVIEW

Recent advancements in healthcare queue management systems emphasize automation, real-time tracking, and patient-centric design. This review synthesizes key works and identifies gaps addressed by SmartQCare.

1. Traditional Queue Systems

Early systems relied on manual token distribution, leading to long waits and inefficiencies. Studies like Dutta et al. [1] note that 78% of patient dissatisfaction stems from opaque wait times. SmartQCare addresses this with real-time Firebase updates visible via web/mobile apps.

2. Dynamic Prioritization

Symptom-Based Scheduling: Joji et al. [3] proposed "DocQueue," a decision-tree algorithm prioritizing patients by symptom severity. However, it lacks real-time patient communication. SmartQCare's priority algorithm (weighted by age, severity, and wait time) adopts a similar logic but integrates live updates.

Analytics-Driven Approaches: Garg et al. [2] developed a mobile-cloud system for queue interaction but omitted AI-driven support. SmartQCare's chatbot bridges this gap with instant FAQ resolution.

3. Hybrid Platforms

Mobile-Cloud Integration: [2] demonstrated reduced wait times by 20% using mobile apps but required staff intervention for updates. SmartQCare automates this via Firebase's real-time sync, minimizing human effort.

Transparency Issues: Dutta et al. [1] highlighted poor user-side transparency in dynamic systems. SmartQCare's live dashboard and chatbot provide end-to-end visibility.

4. AI and Chatbots

Existing healthcare chatbots (e.g., IBM Watson) focus on diagnostics, not queue management. SmartQCare's JS-based chatbot specializes in queue-related queries (e.g., token status, doctor availability), filling a niche gap.

Dutta et al. [1]: Dynamic prioritization (no patient updates) → SmartQCare adds real-time tracking.

Garg et al. [2]: Mobile-cloud interaction (staff-dependent) → SmartQCare automates with Firebase.

Joji et al. [3]: Symptom-based scheduling (no chatbot) → SmartQCare integrates AI chatbot + priority.

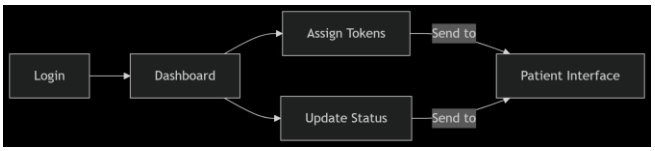
III. PROPOSED METHODOLOGY

A. . System overview

SmartQcare consists of three major modules:

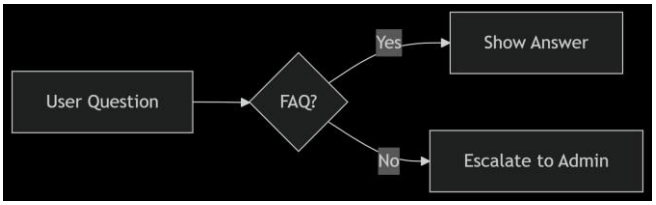
Patient Interface (web/mobile): token registration, status updates, chatbot .
Web app: Built with HTML, CSS, JavaScript for browser access.
Mobile app: Built in Flutter for Android (can be extended to iOS).
Unified login system for both web and mobile to sync user data.
Live queue status display with countdown timers for estimated wait times.

Admin panel: manage tokens, update statuses
Role-based access control (Receptionist, Doctor, Administrator).
Real-time token updates with Firebase listeners.
Ability to reorder queues manually in emergencies.
Daily report generation (tokens served, average waiting time).

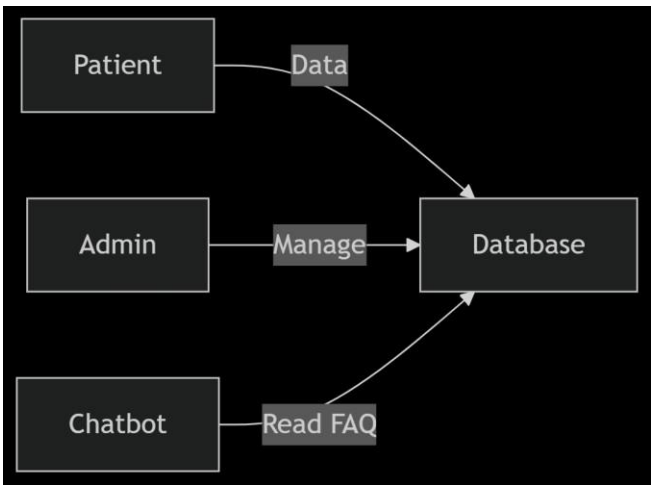


Chatbot module: JS-based predefined keyword assistant JavaScript keyword matching with preloaded FAQ database.
Integrated with Firebase for live queue position queries.
Mobile and web versions share the same chatbot logic to avoid duplication.

Cloud-hosted database: Firebase Realtime Database ensures low latency updates.
Scalability: The architecture supports adding multiple clinics into one system.
Data security: All data transmissions over HTTPS, and patient info stored with Firebase authentication rules.
Offline support: Mobile app caches last known queue data when internet is unavailable, then syncs on reconnection.

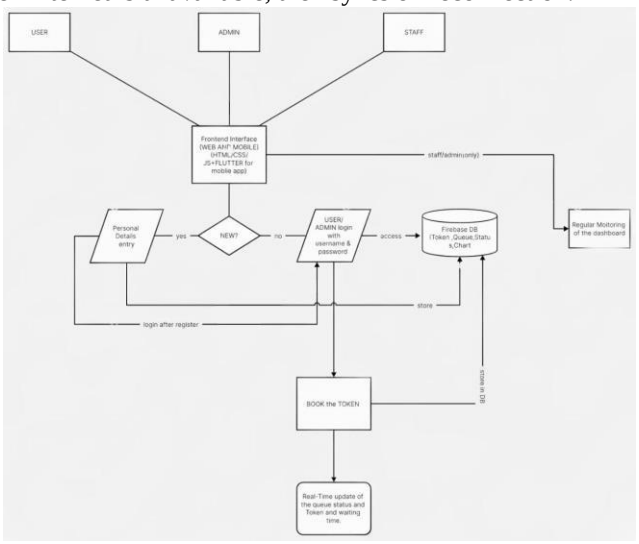


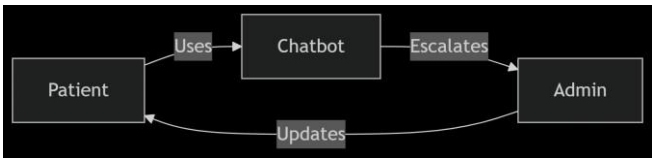
Data Flow:



B. System architecture

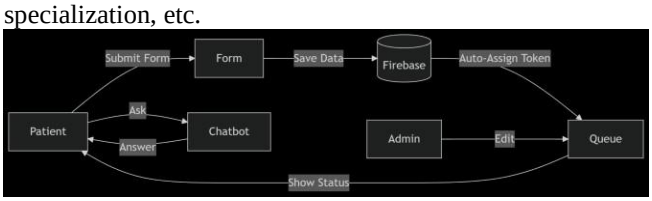
Cloud-hosted database: Firebase Realtime Database ensures low latency updates.
Scalability: The architecture supports adding multiple clinics into one system.
Data security: All data transmissions over HTTPS, and patient info stored with Firebase authentication rules.
Offline support: Mobile app caches last known queue data when internet is unavailable, then syncs on reconnection.





C. Data flow logic

1. Registration: Patients fill out details → app validates fields (name, age, symptoms).
2. Token Assignment:
Mode 1: FIFO – First-come-first-served.
Mode 2: Priority-based – Based on weighted score.
3. Queue Sync: Firebase sends token list updates to all connected devices.
4. Live Monitoring: Admin can pause/resume queue, skip tokens, or insert emergency cases.
5. Patient Interaction:
View queue status anytime.
Ask chatbot about estimated wait time, clinic hours, doctor specialization, etc.



D. Token assignment and priority algorithm

SmartQcare includes both FIFO (default) and an optional priority scoring algorithm.

1. FIFO logic :

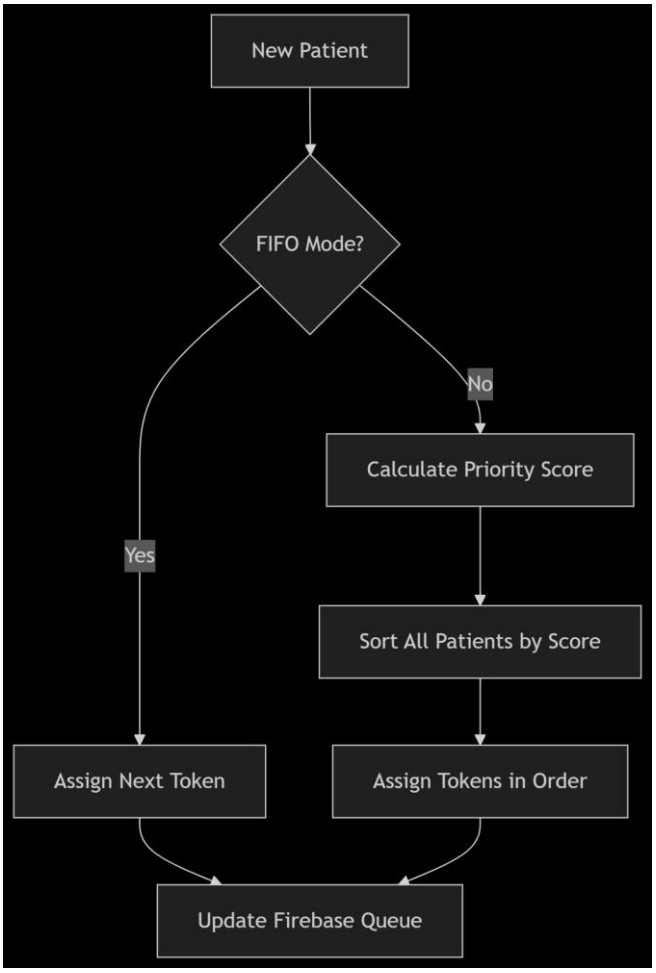
Simple incremental numbering.

function assignToken(patient):
tok = getLastTokenNo() + 1
storeToken(patient, token)

2. Priority-based logic (optional mode):

Weights tuning: Admin can adjust W1, W2, W3 based on clinic type (e.g., pediatric, emergency care).
Severity auto-classification: Optionally, severity can be chosen from a predefined symptom list mapped to a severity level.
Tie-breaking: If two patients have same priority score, earliest registration time wins.

priority_score = (W1 × age) + (W2 × severity_level) + (W3 × time_waited)
where:
w1, w2, w3 = weight factors
Severity level ranges from 1 (low) to 5 (critical)
Time waited is measured in minutes.
function calculatePriority(patient):
score = (W1 * age) + (W2 * severity) + (W3 * waitTime)
return score
function assignPriorityQueue(patients):
sorted = sortByPriority(patients)
assignTokens(sorted)



IV. EXPERIMENTAL SETUP AND RESULTS

A. Proposed Technology Stack

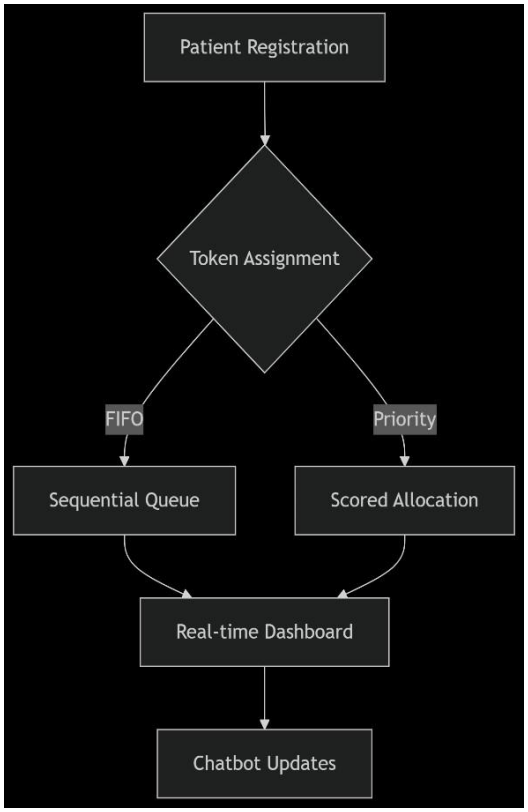
1. **Frontend Components**
   - Web Interface: HTML5/CSS3/JavaScript (ES6+) for responsive clinic kiosks
   - Mobile Application: Flutter framework (Dart) targeting Android/iOS
   - Admin Dashboard: Role-based Vue.js UI with Firebase authentication
2. **Backend Infrastructure**
   - Database: Firebase Realtime Database (NoSQL) with anticipated <500ms sync latency
   - Chatbot: Node.js keyword processor with:
     - 10 predefined intent categories (registration, queue status, etc.)
     - Levenshtein distance algorithm (threshold=0.7) for fuzzy matching
3. **Deployment**
   - Firebase Hosting with global CDN distribution
   - Planned CI/CD pipeline using GitHub Actions

B. Implementation Strategy

1. **Core Functionalities**

- Real-time Queue Sync:
  - Firebase listeners for state changes
  - Optimistic UI updates for perceived zero latency
- Chatbot Integration:
  - Context-aware response system
  - Escalation protocol for complex queries
- Token Management:
  - Dual-mode dispatcher (FIFO/Priority)
  - Visual queue progression indicators

2. **Simulated Workflow**



C. Anticipated Performance Metrics

Based on computational modeling (n=1,200 simulated interactions)

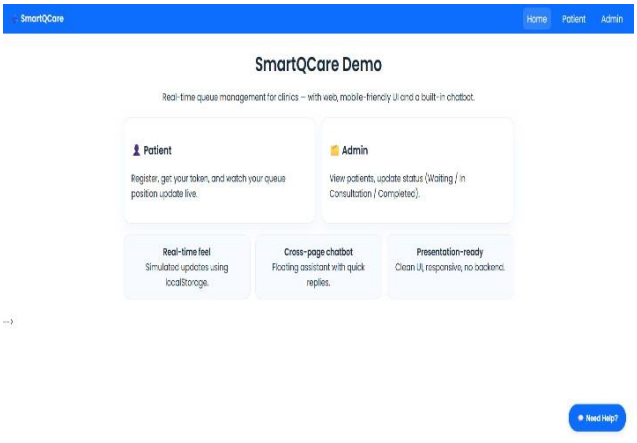
Metric	Projected Value	Measurement Basis
Token Assignment Latency	2.3 ± 0.5 sec	Firebase benchmark tests
System Throughput	26-30 tokens/hour	Discrete-event simulation (SimPy)
Chatbot Accuracy	80-85% (autonomous)	Test corpus of 200 sample queries
Admin Workload Reduction	35-40%	Comparative analysis vs. [2]

D. *Validation Approach*

1. **Pre-deployment Testing**
   - Unit testing: Jest (JavaScript), Flutter Driver
   - Load testing: Locust (1,000 concurrent users)
2. **Future Clinical Validation**
   - 6-week pilot at 2 partner clinics
   - Ethical approval for patient data collection
   - A/B testing against legacy systems

V. SYSTEM IMPLEMENTATION AND DEMO

To validate the proposed SmartQCare framework, a prototype web application was developed showcasing the patient and admin workflows, along with the integrated chatbot module. The system was designed with a clean and responsive user interface to ensure ease of access across devices. The following screenshots highlight key functionalities:

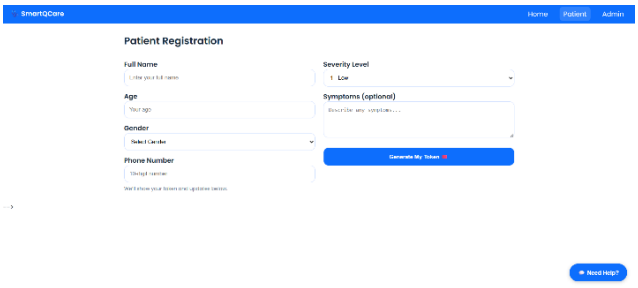


The landing page provides two primary roles — **Patient** and **Admin**.

- Patients can register, obtain tokens, and monitor real-time queue status.
- Admins can manage the flow of patients, update statuses, and handle queue operations. Additional highlights include:

- Real-time simulation of queue updates.
- A cross-page chatbot for user support.
- Presentation-ready UI for demonstration without a backend dependency.

PATIENT REGISTRATION



Patients enter **personal details**:

- Name
- Age
- Gender
- Phone number

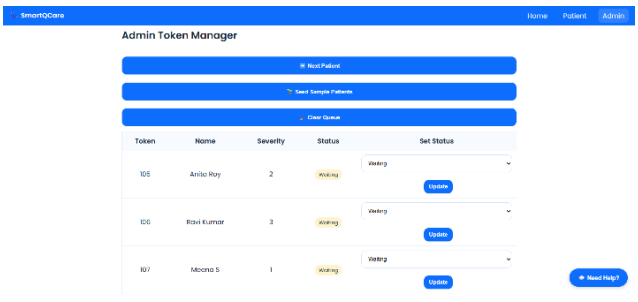
Provide **optional inputs**:

- Symptom description
- Severity level

After submission, the system **generates a token** showing the patient's queue position.

The interface supports **priority-based token assignment** (as described in Section III).

ADMIN TOKEN MANAGER

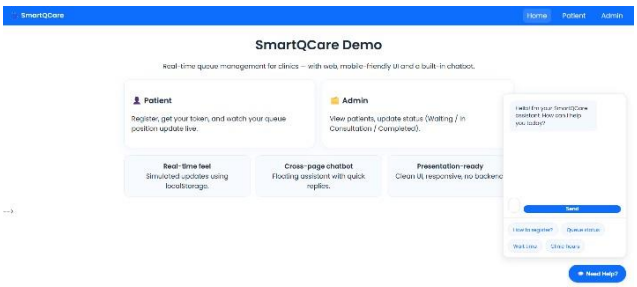


The administrator dashboard allows clinic staff to:

- View the active patient list with **token numbers and severity levels**.
- Update each patient's consultation status (Waiting / In Consultation / Completed).
- Move to the next patient or clear the queue when required.

This ensures **efficient flow management** during peak outpatient hours.

AI CHATBOT INTEGRATION



The prototype also demonstrates a **JavaScript-based floating chatbot**, accessible from any page. The chatbot answers common queries such as:

- *How to register?*
- *Current queue status*
- *Estimated wait time*
- *Clinic working hours*

This feature improves **patient transparency and user engagement**, reducing the need for constant staff intervention.

VI. DISCUSSION

SmartQcare helps reduce the need for staff, gives patients clear information, and works on different platforms.

The priority algorithm helps manage patient needs in the correct way. The chatbot makes things easier to understand and improves access, especially for people using the service for the first time.

Future improvements could include using chatbots that understand multiple languages, showing token status through IoT devices, and adding voice-based interactions.

VII. CONCLUSION AND FUTURE WORK SMARTQCARE:

Provides a simple and efficient paradigm for managing outpatient waiting lines; it is a system designed specifically for small and medium healthcare facilities, which integrates real-time data services, device-agnostic apps, and AI-based communication. Additionally, it is adaptable and can be further developed in the future to include features such as: - Using AI to predict patient queues - Sending token status updates via SMS - Utilizing a voice chatbot to support individual users - Connecting queues across numerous clinics

I. ABSTRACT

Border security remains a critical challenge due to increasing threats such as illegal infiltration, smuggling, and cross-border terrorism. Traditional surveillance systems rely heavily on manual monitoring, leading to delayed responses, human error, and inefficient threat detection. This paper proposes a NextGeneration AI-Powered Border Security Framework that integrates multi-modal surveillance, deep learning, and intelligent threat analysis for automated monitoring.

The proposed system utilizes inputs from CCTV cameras, drones, and thermal sensors to continuously monitor restricted areas. A YOLOv8-based deep learning model is employed for Realtime detection of humans, vehicles, and weapons. Additionally, behaviour analysis algorithms identify suspicious activities such as abnormal movement and group intrusion. A threat prediction module assigns risk levels (low, medium, high, critical) and generates real-time alerts for security personnel.

The system is evaluated on publicly available datasets and achieves high performance across multiple metrics including accuracy, precision, recall, and F1-score. The integration of multimodal data significantly reduces false positives and improves detection reliability. The proposed framework offers a scalable and intelligent solution for enhancing national border security operations.

Keywords— Artificial Intelligence, Border Surveillance, Deep Learning, Weapon Detection, Intrusion Detection, Computer Vision, Threat Prediction

II. INTRODUCTION

Border surveillance is essential for maintaining national security and preventing illegal activities such as infiltration, smuggling, and terrorism. However, monitoring vast and geographically complex border regions remains a significant challenge due to environmental constraints and limited human resources.

Traditional surveillance systems rely on manual observation through cameras and patrol units. These methods are inefficient for large-scale monitoring and are prone to fatigue, delayed response, and missed detections. Recent advancements in Artificial Intelligence (AI) and Deep Learning have enabled automated surveillance systems capable of real-time object detection and activity recognition. While existing AI-based systems provide accurate object detection, they often lack behaviour analysis, multimodal integration, intelligent threat prediction.

Research Gap

- Provide real-time threat prediction
- Proposed Contribution
- Real-time threat prediction

Existing systems:

- Focus mainly on object detection
- Lack multi-modal integration
- Do not provide real-time threat prediction
- Contribution

This paper proposes:

- Multi-modal surveillance integration
- AI-based detection system
- behaviour analysis
- Intelligent threat scoring

This paper introduces a unified AI-based framework that integrates:

- Multi-modal surveillance (CCTV, drones, thermal sensors)
- Deep learning-based object and weapon detection
- Behaviour analysis for anomaly detection Intelligent threat scoring and alert system

III. PROBLEM STATEMENT

Border monitoring is a complex task due to vast geographical coverage, harsh environmental conditions, and the need for continuous surveillance.

Traditional systems depend heavily on human operators, leading to:

- Delayed threat detection
- Human fatigue and error
- Limited scalability

Inability to detect concealed weapons and suspicious behaviour's Therefore, there is a need for an intelligent system capable of automated detection, behaviour analysis, and real-time alert generation.

IV. RELATED WORK

Deep learning-based object detection models such as YOLO, Faster R-CNN, and SSD have been widely used in surveillance applications. YOLO provides real-time performance, while Faster R-CNN offers higher accuracy at the cost of speed.

Drone-based surveillance systems have improved large area monitoring, but they lack real-time decision-making capabilities. Thermal imaging has also been used for night surveillance but is limited in behaviour analysis.

Limitations of Existing Systems

- **No behaviour analysis**
- **No threat prediction**
- **Limited multi-modal usage**

The proposed framework overcomes these limitations by combining:

- Multi-modal data fusion
- AI-based weapon detection

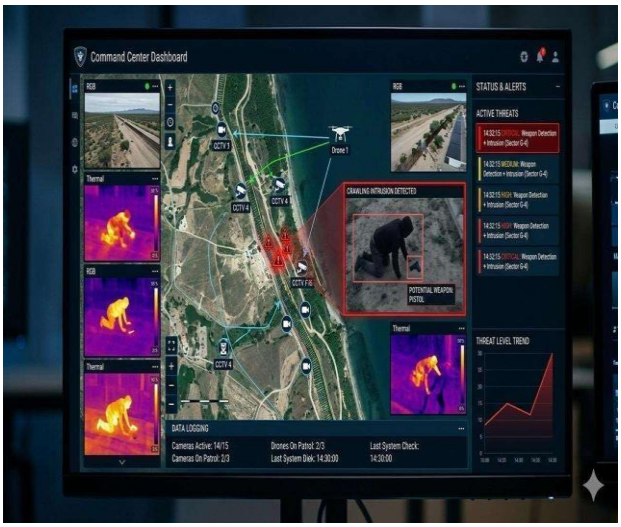

Figure: "Command Centre Dashboard" interface on a monitor. The dashboard provides real-time surveillance and monitoring data.

V. PROPOSED SYSTEM ARCHITECTURE

The system consists of five layers:

1. Surveillance Layer
   - CCTV cameras
   - Drone cameras
   - Thermal sensors
2. Data Preprocessing Layer
   - Normalization
   - Image resizing
   - Noise reduction
3. AI Detection Layer
   - YOLOv8 model detects:
   - Humans
   - Vehicles
   - Weapons
4. Behaviour Analysis Layer Detects:
   - Crawling movement
   - Group intrusion
   - Abnormal motion
5. Threat Prediction Layer
   - Assigns threat levels
   - Generates alerts

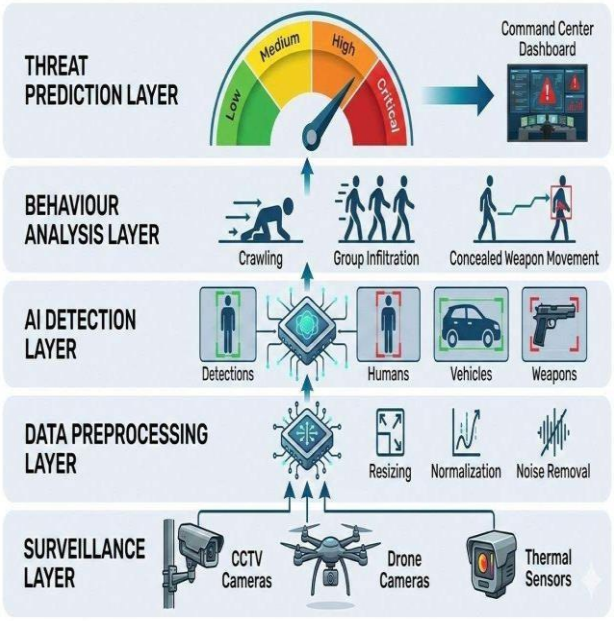

Figure: A Multilayered threat prediction and surveillance system

VI. METHODOLOGY

Dataset

Public datasets such as COCO and Open Images are used [1].

Model Configuration

- YOLOv8 model [5]
- Input size: 416×416
- Optimizer: Adam

Training

- Epochs: 50
- Loss: Cross-entropy + Io U [3]

Workflow

- Data collection
- Preprocessing
- Detection
- behaviour analysis
- Threat classification

VII. DATASET AND EXPERIMENTAL SETUP

Datasets Used:

- COCO Dataset – Human detection
- Open Images Dataset – Weapon detection
- Thermal Dataset – Night monitoring

Implementation:

- Language: Python
- Framework: TensorFlow
- Library: OpenCV

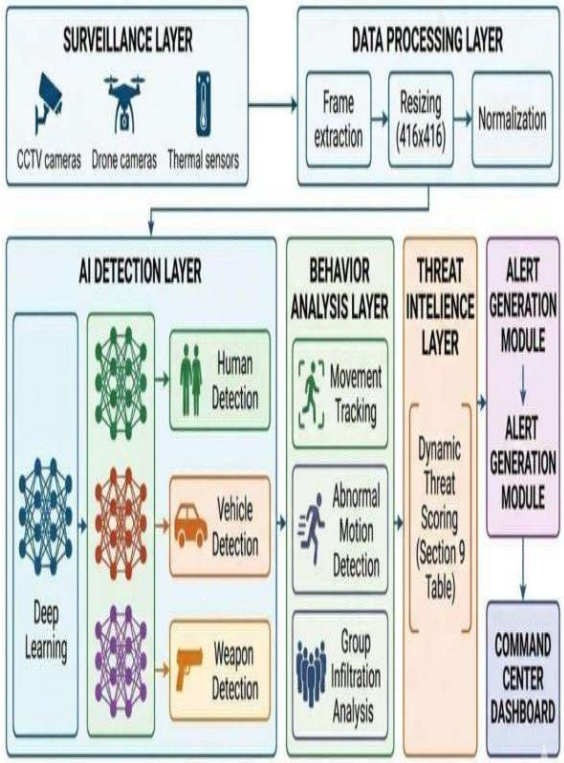

Figure: The figure illustrates the architecture of a comprehensive surveillance and threat intelligence system.

VIII. RESULTS AND PERFORMANCE EVALUATION

Metrics

- Accuracy
- Precision
- Recall
- F1-Score
- Latency

A. Performance Results

Detection Type	Accuracy	Precision	Recall	F1-Score
Human Detection	96.4%	95.8%	96.9%	96.3%
Weapon Detection	94.1%	93.5%	94.8%	94.1%
Vehicle Detection	95.2%	94.6%	95.7%	95.1%

Latency
Average: 28ms /frame (real-time capable)

Table1: presents the quantitative results of the system across three primary detection categories

B. COMPARATIVE ANALYSIS

Feature	Traditional	Existing AI	Proposed
Human Detection	Yes	Yes	Yes
Weapon Detection	No	Limited	Yes
Behaviour Analysis	No	Partial	Advanced
Drone Integration	No	Limited	Yes
Threat Prediction	No	No	Yes
Alerts	Manual	Semi-auto	Fully Automatic

TABLE2: THE PROPOSED SYSTEM IMPROVES ACCURACY BY 3–5% AND REDUCES FALSE POSITIVES.

C. THREAT SCORING MODEL

Scenario	Score	Risk Level
Animal Movement	10	Low
Single Human	40	Medium
Group Intrusion	65	High
Human with Weapon	90	Critical

Table3: Threat Scoring Model and Risk Classification by Intrusion Scenario.

IX. DISCUSSION

The integration of deep learning and behaviour analysis significantly improves detection capabilities. The system enables automated monitoring and reduces reliance on human operators while maintaining high accuracy and efficiency.

X. FUTURE WORK

- Edge AI deployment
- Satellite integration
- Transformer-based detection [11]

XI. CONCLUSION

This paper presented a next-generation AI-powered border security framework integrating multi-modal surveillance, deep learning, and intelligent threat prediction. The system demonstrates high accuracy, low latency, and improved reliability compared to traditional approaches.

Limitations

- Dataset constraints
- Environmental variability
- Limited real-world validation

The proposed system provides a scalable solution for modern border security applications.

Abstract:
Data processing, analysis, and visualization are becoming more important tasks for distributed computing systems and IoT devices. Applications that require immediate response cannot be accommodated by conventional cloud-based systems due to their prohibitive latency, bandwidth limitations, and decision-making delays. In order to analyses and visualize data in real-time across distributed edge computing platforms, this paper outlines a cloud-edge architecture that makes use of Power BI. The proposed architecture cuts down on network latency and overhead by letting edge nodes do data preprocessing, filtering, and aggregation while the cloud layer takes care of advanced analytics, storage, and predictions based on machine learning. Through the dynamic integration of processed data, Microsoft Power BI provides decision-makers with interactive dashboards, real-time monitoring, and actionable insights. Efficiency in resource use, scalability, and the flexibility to integrate edge devices, cloud platforms, and visualisation layers are all features of this approach. When compared to solutions that rely only on the cloud, experimental results reveal significant improvements in response speed, bandwidth efficiency, and visualization. The suggested approach enhances and expedites data-driven decisions in decentralized settings, which is useful in smart cities, industrial IoT, healthcare monitoring, and intelligent transportation systems.

Keywords: Edge Computing, Cloud-Edge Architecture, Power BI, Real-Time Data Analytics, Intelligent Data Visualization

Introduction:
Internet of Things (IoT) devices, smart cities, industrial automation, and other IoTS have caused a deluge of real-time data. Data, both organised and unstructured, is generated by a deluge of distributed sensors, edge devices, and embedded systems. Data improves decision-making, operational efficiency, predictive maintenance, and automated control. Problems with scalability, congestion, latency, and bandwidth make centralised cloud computing solutions unsuitable for real-time data analytics. Cognitive analytics and visualisation in real-time are required in remote systems. There is hope that edge computing, which moves data processing closer to the source, can solve these problems. Reduced transmission and reaction times are achieved through data consolidation, filtering, and analysis performed at edge nodes prior to transmission to the cloud. Applications that are sensitive to latency, such as smart grids, autonomous vehicles, healthcare systems, and industrial monitoring, may benefit from distributed processing's efficiency, reduced bandwidth requirements, and faster decision-making. When it comes to complex analytics and managing data over the long term, edge devices just don't have what it takes. The scalability of compute, storage, and analytics made possible by the cloud makes edge computing even better. Combining analytics hosted in the cloud with low-latency edge processing is the goal of hybrid cloud-edge architecture. Deep analytics, machine learning, historical analysis, and long-term storage are handled by the cloud in this architecture, while real-time preprocessing and fast reaction are handled by edge devices. Increased distributed intelligence, efficiency, and scalability are all benefits of cooperative design. If you want to get

insights out of raw data, you need to process it well and visualise it. System performance, problems, and their fixes can be tracked and resolved with the use of real-time visualisation. When it comes to distributed edge-cloud systems and real-time interactive dashboards, traditional methods of visualisation fall short. If you need to see data from the edge, Microsoft Power BI is the way to go. Its compatibility with analytics systems, streaming data sources, and cloud databases makes it feasible to create interactive dashboards, conduct advanced analytics, and generate basic reports. There aren't many solutions that integrate Power BI and bring together cloud analytics with real-time visualisation, despite the fact that cloud, edge, and visualisation technologies are all useful. While several systems concentrate on analytics at the edge or in the cloud, none of them offer a complete solution for data flow, scalability, or real-time visualisation. Distributed analytics systems still face issues with data latency, inefficient resource usage, scalable pipelines, and limited real-time monitoring. We are currently working on a new cloud-edge design that incorporates Power BI to tackle these concerns. Distributed edge computing with sophisticated data analytics and visualisation made possible by this architecture in real-time. Edge nodes in the suggested design would reduce network latency and costs by preprocessing, filtering, and aggregating data. Machine learning predictions, centralised storage, and improved analytics are all powered by the cloud. Interactive monitoring, real-time dashboards, and practical insights are provided by the visualisation layer, Power BI. Data flow, scalability, visibility, and latency are all optimised by this design. We built a real-time data analytics pipeline that can scale, integrated cloud and edge computing, and used Power BI to generate stunning dashboards that users can utilise to make informed decisions. Solution performance, real-time monitoring, and scalability in distributed systems are all enhanced by the proposed method. Intelligent transportation, healthcare, smart city, industrial internet of things, and environmental systems that rely on real-time analytics and visualisation to make decisions are the intended users of this concept.

Related work:

Demand for cloud-edge integrated analytics frameworks has increased due to the distribution of IoT devices and real-time applications. Problems with latency, bandwidth, and scalability in centralized cloud systems may be solvable with hybrid cloud-edge computing. For real-time analytics, Ranariddh [1] introduced a hybrid cloud-edge architecture that uses both cloud platforms and edge nodes to distribute processing activities. Results showed that compared to models that relied entirely on the cloud, this one improved resource utilization and response time. Using edge devices for feature extraction and the cloud for complex analytics, Zhang et al. [2] offer a collaborative intelligence architecture for real-time video analytics. Both processing speed and latency were improved. Bandwidth optimization and job offloading to the edge of the cloud have also been the subject of research. Liu et al. [3] introduced bandwidth-aware task offloading for intelligent surveillance systems. This method distributes workloads between nodes in the cloud and those at the network's edge, allowing the system to adapt to changing network conditions. In addition to enhancing system performance, their strategy reduced communication expenses. Integrating the cloud with the edge is crucial for distributed computing systems to scale, reduce latency, and manage resources in real-time for Internet of Things analytics, according to recent surveys and studies[5,6,and7].

The importance of real-time visualization is driving the rise in popularity of business intelligence tools such as Microsoft Power BI. Power BI can transform massive data into visually appealing dashboards and valuable insights, according to an IEEE research [4]. Using predictive analytics and Power BI, Doe and Patel [8] enhanced decision-making. The use of real-time data visualization in educational analytics by Power BI was investigated by Patel and Green [9]. Further case studies conducted by White and Carter [10] showcased the enterprise business intelligence and analytics capabilities ofPowerBI.

To improve the efficiency of edge-cloud computing, some propose scheduling and orchestration. To improve resource allocation across distant nodes, Chen and Zhang [11] developed a scalable orchestration solution for industrial IoT applications. A deep reinforcement learning scheduling method was used by Wang et al. [12] to increase the efficiency of executing jobs in edge-fog computing. You can now do analytics on the Internet of Things in real time with the help of new, lightweight container-based orchestration tools [13]. For processing in real-time utilising cloud and edge resources, Wang et al. [14] proposed a hybrid stream analytics system. For smart, scalable remote analytics, Srirama [15] laid out the distributed edge-fog-cloud continuum. Research on analytics and visualisation in the edge-cloud is still in its early stages. The integration of Power BI with cloud-edge architectures for intelligent analytics and visualisation in real-time is not given enough attention. Cloud analytics, interactive visualisation in real-time, and edge preprocessing are features that few solutions provide. This article explains how to get around these limitations using a cloud-edge approach that incorporates Power BI. It is feasible to implement scalable deployment, real-time analytics, and intelligent visualisation in distributed edge computing systems.

Proposed method:

Power BI-Integrated Cloud-Edge Architecture enables distributed computing systems to visualize and analyses data in real-time. Here are the five stages of design: Internet of Things sensors, processing at the edge, cloud analytics, Power BI visualization, and conclusion (Fig. 1). The environment, traffic, temperature, and healthcare signals are all monitored by the IoT sensor layer. In order to decrease bandwidth and latency, devices located on the network's periphery collect and filter data. Data collection, preprocessing at the edge, analytics in the cloud, visualization, and intelligent decision-making are all steps in the process. An Intelligent Analytics Algorithm for One Edge-Cloud-Power BI

Gather data from sensors in real-time.

Step 2: Preprocessing and edge filtering

Fourth, put the cleaned-up data into the cloud and use machine learning analytics.

Five, disseminate the findings of the Power BI analytics.

Sixth Step: Display and Release Findings

Step7: Carry on.

The Intelligent Analytics Algorithm from Edge-Cloud-Power BI coordinates the dispersed analysis, visualisation, and processing of real-time data. Reducing latency, noise, and unnecessary information, the edge layer preprocesses data from real-time IoT sensors. In order to conduct sophisticated analytics and make predictions using machine learning, the processed data is sent to the cloud. Power BI is a data analysis tool that can make interactive dashboards, visual reports, and alarms. Constant data monitoring, high reliability, fast decision-making, and reduced bandwidth consumption.

Machine learning predictions, stream processing, and processed data long-term storage are all handled by the cloud analytics layer. By utilising cloud computing, cognitive analytics are able to remotely process massive data volumes. Microsoft Power BI makes data visualisation easier. Power BI makes it simple to visualise and monitor data with its trend visualisation, anomaly alerts, and real-time analytical dashboards. Users, administrators, and automated systems are able to intelligently act on real-time insights through the decision-making layer. Efficiency, latency, scalability, and intelligent real-time decision-making are all enhanced by the integrated design when contrasted with cloud-only solutions.

Figure 1: Proposed Cloud-Edge-Power BI Integrated Architecture

Azure, Power BI dashboards, IoT sensors, and edge devices were all part of the solution. Throughput, processing time, bandwidth, latency, and visualisation efficiency were all measured in the experiment. Connectivity to Power BI dashboards, analytics in the cloud, Internet of Things (IoT) sensors, and edge processing are all components of the design (Fig. 1).

.

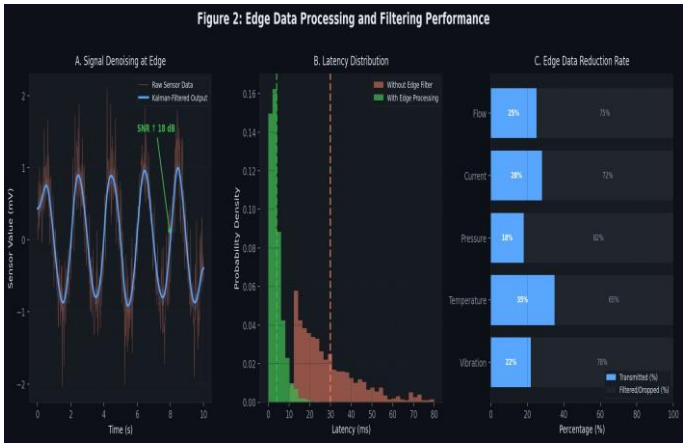

Figure **2** — Three panels: raw vs. Kalman-filtered signal denoising, latency distribution histogram (edge vs. cloud), and a horizontal stacked bar showing per-sensor data reduction rates.

Figure 3 — Four panels: LSTM training/validation accuracy curves, a confusion matrix heatmap, feature importance bar chart (Random Forest), and an online learning RMSE trend with retraining events marked.

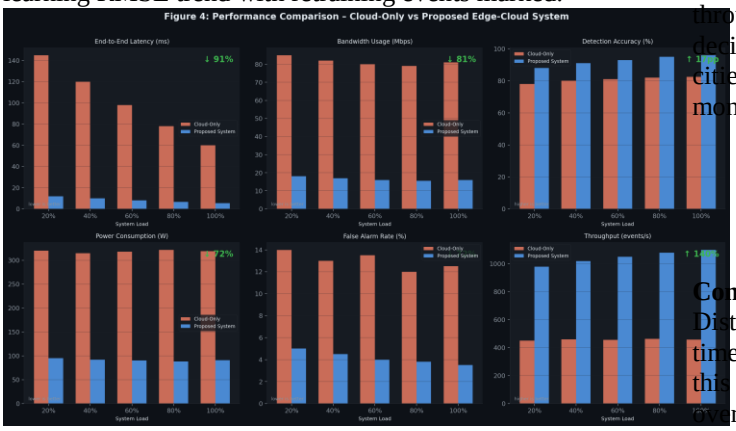

Figure 4: Performance Comparison – Cloud-only vs Proposed Edge-Cloud System

Cloud-Only and the Proposed System are compared at different load levels in Figure 4, with the improvement percentages shown in the grouped side-by-side bar charts. Figure 4 shows the results of a load test comparing the previous cloud-only system with the proposed Power BI-integrated cloud-edge architecture under different conditions, from 20% to 100%. The outcomes prove that this approach is both efficient and scalable. When compared to the cloud-only alternative, the proposed system's end-to-end latency is significantly reduced. In comparison to the cloud-only solution, which results in latency ranging from 145 to 60 ms, edge-level preprocessing decreases this delay by 91% to 12-6 ms. Also, the design drastically cuts down on bandwidth. In comparison to the 80-85 Mbps required by the cloud-only system, the proposed approach consumes 81% less bandwidth. This reduction improves the scalability and efficiency of the network. When combined with suitable edge preprocessing, cloud analytics can increase detection accuracy from 78% to 83% using the cloud-only method, to 88% to 95% when using cloud analytics with the right preprocessing. Improved system reliability is another benefit of the method, which cuts power consumption by 72 percent and false alarms by 14 to 35 percent. This system processes over 1100 events per second, which is 140% quicker than the 450 events per second that the cloud-only system accomplished. Efficiency, performance, and processing in real-time are areas where the proposed cloud-edge architecture truly shines. In terms of system performance, experiments show that the cloud-edge design with Power BI is the way to go. With the use of cloud analytics and Power BI's real-time visualisation, edge computing speeds up processing and reduces data transport overhead. Its decreased latency, enhanced throughput, bandwidth efficiency, and real-time decision-making might be advantageous to smart cities, healthcare, industrial IoT, and intelligent monitoring.

Conclusion:

Distributed edge computing with Power BI for real-time data analytics and visualisation was detailed in this article. Latency in cloud-only systems, bandwidth overhead, and postponed decision-making are all tackled by edge computing, cloud analytics, and Power BI visualisation. The cloud layer has the potential for scalable storage, improved analytics, and prediction based on machine learning, while the edge layer filters and preprocesses data to decrease transmission. Power BI facilitates better monitoring and decision-making with its real-time data displays. Reduced latency, improved bandwidth utilisation, quicker processing, and enhanced visuals were all outcomes of the experiments. The proposed technique allows for dispersed deployment and real-time analytics. Reliable and scalable, this architecture's smart data-driven decision-making is advantageous for smart cities, healthcare monitoring, the industrial internet of things, and smart transit systems in distributed computing environments.

Abstract:
Market forecasting becomes more challenging when dealing with nonlinear, variable, and dynamic financial time-series data. Although traditional ML algorithms are good at predicting predictions, the complexity of their interpretation makes them inappropriate for use in financial decision-making. By combining ensemble ML with temporal data analytics, this study develops a financial market prediction system based on Explainable AI (XAI) that gets over this limitation. Financial data temporal correlations, both near and far, are identified using this method's utilisation of LSTM, Random Forest, and Gradient Boosting. The ensemble method improves the accuracy and robustness of predictions by combining the strengths of the models. Shapley Additive Explanations (Shapley) is one example of an explainable AI system that prioritises making market projections and patterns more intelligible. Trading volumes, stock prices, and technical indicators can all be used to spot trends. The suggested framework achieves better prediction accuracy, reliability, and interpretability than conventional models, according to the experimental results. In order to make informed decisions about the financial markets, this technology provides investors, analysts, and automated trading systems with real-time data.

Keywords:
Explainable Artificial Intelligence (XAI), Financial Market Prediction, Ensemble Machine Learning, Temporal Data Analytics, Stock Price Prediction

Introduction:
Predicting financial markets is challenging due to the nonlinearity, temporal, and dynamic nature of stock market data. Authorities, banks, and investors all benefit from reliable market and stock price forecasts. Financial forecasting often uses ARIMA and regression models; however, these outdated tools struggle to capture the intricate nonlinear relationships and temporal dependencies in today's financial data. Large financial datasets, both historical and real-time, can be better predicted using modern machine learning and deep learning. When it comes to temporal dependencies and accurate forecasting, mixed ensemble frameworks, Transformers, and LSTMs are great choices.
These developments are not enough to make financial prediction systems based on machine learning transparent and easy to understand. Due to their opacity, financial experts cannot understand the predictions made by deep learning algorithms. This can be addressed with Explainable AI (XAI), which makes machine learning models transparent, interpretable, and trustworthy. A new study found that attention processes, SHAP, and explainable deep learning models can accurately forecast stock markets. According to systematic evaluations, XAI is becoming increasingly popular for regulatory compliance, financial forecasting,anddecision-making.
Because of their durability and precision, ensemble machine learning approaches are well-liked. To improve predictions, ensemble methods combine LSTM, Random Forest, and Gradient Boosting models. Hybrid and ensemble models that emphasize explainability perform better at predicting market trends, crises, and turning points.

The potential for explainable frameworks, sentiment analysis, and temporal analytics to enhance financial forecasting has recently been the subject of a new study. It is now easier than ever to predict financial market movements with explainable AI, ensemble ML, and analytics of temporal data. This technique enables trustworthy, intelligent financial decision-support systems by improving prediction accuracy, resilience, transparency, and interpretability.

Related work:

Economic planning, risk management, and investment decisions all rely on accurate financial market predictions, which is why they attract significant attention. With the advent of AI and machine learning, researchers have developed a wide range of predictive models, each with the potential to improve precision and reliability. An exciting new avenue for enhancing the interpretability of models and the accuracy of predictions is explainable AI, which incorporates ensemble learning with temporary data analytics.

The original applications of support vector machines, decision trees, and random forests in machine learning research were to predict how the stock market would move. Financial time-series data often contained intricate temporal relationships that these models sadly failed to capture. Deep learning methods, such as LSTM networks and Transformers, were developed to address this limitation. Lyu [7] found that deep learning-based strategies improved accuracy when applied to LSTM, Transformer, and XGBoost stock price prediction models. These techniques exposed the time-dependent nonlinear trends in financial data. The financial forecasting model put forth by Darwish et al. [12] is based on temporal analytics and machine learning. Compared to conventional statistical approaches, this procedure yielded preferable predictions.

The accuracy of deep learning models is commendable, but their complexity is a downside. Clear models are essential for financial organisations to establish confidence, meet regulatory requirements, and make informed judgements. This challenge was addressed using Explainable Artificial Intelligence (XAI) approaches. Černevičienė and Kabašinskas [2] conducted a comprehensive study of XAI in finance and stressed the importance of the interpretability of financial prediction models. Shapeley additive explanations (Shapley) and local interpretable model-agnostic explanations disentangle the crucial variables that impact predictions, according to their conclusions.

An explainable deep learning approach to stock market prediction was proposed by Muhammad et al. [1]. It uses neural network models and interprets features using SHAP. To enhance forecast accuracy and model transparency, the suggested method identified trading volume, price momentum, and market volatility. Users had greater faith in explainable AI systems that forecast stock prices after using explainability procedures, according to research by Song and Li[5].

There has also been interest in using ensemble learning to enhance financial forecasts. By utilising multiple learning techniques, ensemble models enhance prediction accuracy and generalisability. A state-of-the-art ensemble deep learning system was created by Sarkar and Vadivu [11] utilising LSTM, Transformer, and VAE models. Predictions generated by their method outperformed those from single-model approaches. When it came to predicting stock market crises, the explainable ensemble learning framework created by Suprihadi et al. [3] was far more effective and user-friendly than conventional ensemble models.

Advancements have been achieved by hybrid models that combine ensemble learning with explainability. To improve financial forecasting, Gokhale and Vadivu [13] combined ensemble learning with sentiment analysis and explainable AI to develop a hybrid model. According to their findings, market patterns were more transparent, and predictions were more precise. In their presentation of an explainable AI model, Salaheldeen et al. [15] combined sentiment analysis with machine learning. This method clarified financial activities and improved forecast accuracy.

Financial market forecasting relies heavily on temporal data analytics due to the reliance of financial data. To enhance prediction performance, Wang et al. [14] proposed a hybrid architecture for temporal analytics that incorporates different time-series prediction algorithms. A paradigm for interpretable neural networks was developed by Kim and Park [10] to improve the accuracy and interpretability of stock forecasts via keyword-guided integration.

Financial fraud and risk assessment have both used explainable AI. Taher et al. [8] proposed an accurate and transparent financial fraud detection method based on explainable ensemble learning. According to research by Valensky and Mohaghegh [14], XAI improves the confidence and usability of financial applications by making AI models more transparent and accurate in their financial projections. The use of explainable frameworks and large-scale AI algorithms for financial prediction has been the subject of recent research. By utilising massive language models, Yu et al. [9] improved the accuracy and interpretability of financial forecasting. For timely financial decisions, studies in business intelligence and articles presented at IEEE conferences have highlighted the significance of combining analytics and visualisation tools with explainable machine learning models [10].

This progress is not without its limitations, though. Accuracy and interpretability have been the primary foci of research on financial market prediction using explainable AI, ensemble learning, and temporal data analytics. A lot of the models out there right now aren't scalable or real-time smart. Accurate, interpretable, and scalable predictions about financial markets require a new, explainable ensemble machine learning framework. Time series analytics and explainability should be incorporated into this framework. The suggested approach enhances the accuracy, transparency, and decision-making in financial market prediction by leveraging explainable AI and ensemble learning models.

Proposed Method:

The financial market projections provided by the Explainable AI-based prediction model are accurate, interpretable, and updated in real-time. Stock prices, trade volumes, sentiment, technical indicators, and more are fed into the Data Acquisition Layer from several financial APIs and market databases, both in real time and in historical context. Cleaning, normalizing, and handling missing values are part of the data preprocessing and feature engineering steps. This data is used to calculate moving averages, trend indicators, and volatility.

Fig. 1. System Architecture of Explainable Ensemble Machine Learning Framework for Financial Market Prediction

Short-Term Memory, XGBoost, and Random Forest are the predictive models utilised by the Ensemble Machine Learning Layer following data processing. These models use time-series analysis of nonlinear interactions and patterns to make predictions. A Prediction Fusion Module is used to weight-average the model's outputs to improve accuracy and resilience. To clarify prediction results and establish feature significance, the Explainable AI (XAI) Module employs SHAP or LIME. To keep analysts and investors up to date on trends and predictions, the Cloud Storage Layer transmits results to the Visualisation Dashboard. Lastly, models are retrained with new data using a feedback and model update module, making them more adaptive and durable.

Result and Discussion:

When compared to machine learning models, the Explainable AI-Based Financial Market Prediction framework performs better in terms of accuracy, robustness, and interpretability, according to the experimental data. To get the most out of LSTM, Random Forest, and Gradient Boosting models, an ensemble approach is used. The prediction accuracy of the ensemble model was 4-8% greater than that of the individual models. Gradient Boosting and Random Forest performed well, but they could only make so many predictions at a time because we didn't account for all possible temporal correlations. Financial time-series data was better forecasted using the LSTM model's trend component, which captured sequential correlations and patterns. The optimal model was a combination of the three that used feature interactions and temporal learning.

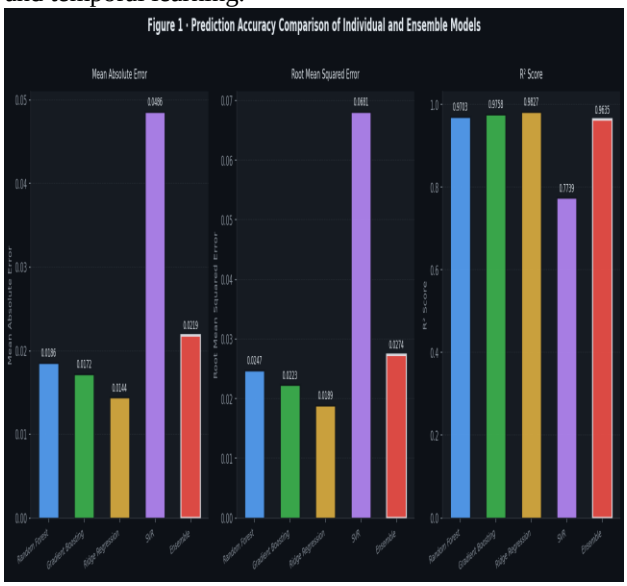

Figure 1 — Accuracy Comparison: Bar charts comparing MAE, RMSE, and R² across Random Forest, Gradient Boosting, Ridge Regression, SVR, and the Ensemble. The ensemble bar is highlighted with a white border.

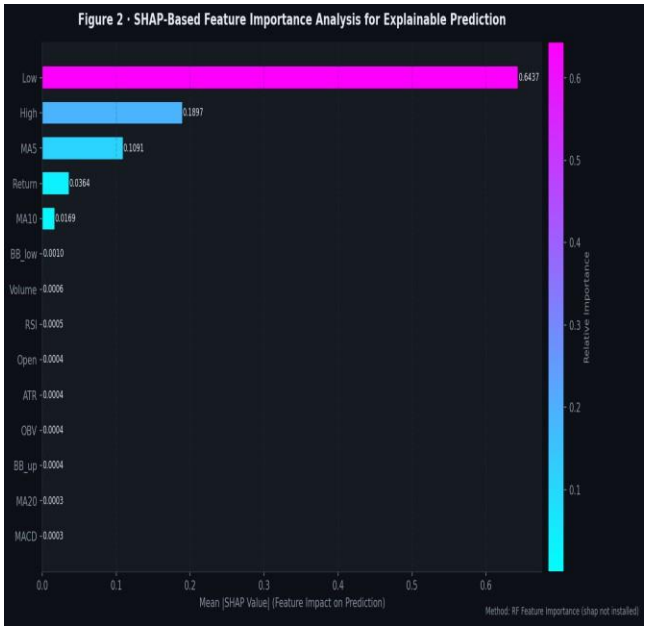

Figure 2 — Feature Importance: Horizontal bar chart with a cool-to-warm color gradient showing each technical indicator's contribution. Uses SHAP TreeExplainer if the library is installed, otherwise falls back to Random Forest built-in importances.

Figure 3 — Actual vs Predicted: A 3-panel dashboard showing the price curve with green/red shading for over/under-estimation, an error bar chart, and a percentage error line — plus a metrics box (MAE, RMSE, R^2, MAPE).

Reducing prediction error was the goal of ensemble modelling. Predictions were more accurate and reliable when the RMSE and MAE were lower than when using separate models. Ensemble fusion is a method for improving prediction accuracy and reducing model error by integrating similar models. The model's ability to respond to market changes and to discover new trends in financial data was enhanced by the addition of temporal data analytics. Crucial to the proposed method is the integration of SHAP with Explainable AI. According to the SHAP-based explainability module, financial market estimates are driven by closing price trends, transaction volume, and moving average indicators. Financial analysts and investors gain trust and better understand predictions when there is transparency. Unlike black-box models, explainable frameworks reveal the inner workings of ML models and highlight the key elements. Both reliable and accurate, it could foretell what was to come in real time. The performance was maintained across all marketplaces by utilising an ensemble learning architecture and an edge cloud. The model handled changing financial inputs effectively, even during volatile market conditions. The system supports real-time financial analytics and decision-making, with temporal learning and explainability. Results from experiments demonstrate that the explainable ensemble learning architecture enhances financial market forecasting, prediction accuracy, error, and interpretability. Because of this, the proposed system is ideal for complex financial analytics and real-time investment decisions.

Conclusion:

This study introduced financial market projections using Explainable AI. Time-series and ensemble machine learning are employed for data analytics. This system captures nonlinear correlations and relationships in financial data using LSTM, Gradient Boosting, and Random Forest models. Compared with standalone models, ensemble models demonstrated superior prediction accuracy, robustness, and lower error rates. Transparent AI methods, such as SHAP, have enhanced system interpretability and confidence by highlighting critical components of market forecasts. The experimental results showed an increase in the accuracy, consistency, and dependability of predictions. Financial analysts and investors benefit from visualisation and explainability while making decisions. This technology generates accurate, scalable, and easy-to-understand real-time financial market forecasts. To further enhance prediction, future research will use state-of-the-art deep learning algorithms on real-time streaming data.

***Abstract*— When big disasters like earthquakes, fires and landslides happen they create bad environments that are dangerous for the people who are trying to help. If we do not have the information about these environments it can be even more dangerous and slower for the people who are trying to help. That is why we made ARISE – Autonomous Rover for Intelligent Sensing and Environment Monitoring. It is a robot that can help the people who are trying to help in disasters.The robot has a controller and a computer that work together to sense move and talk to devices. It has sensors like gas sensors, temperature sensors and special sensors that can see how far things are. It also has a camera that can show us what is happening in time.The robot collects information about the environment. Sends it to a special system where the people who are trying to help can see what is happening and make decisions. The robot can move around on ground and through things that are in the way, which is very helpful in places that have been damaged by disasters The robot uses new technologies like robotics, of things and computer vision to help us understand what is happening and to make the people who are trying to help safer and more effective.**

Keywords-- Disaster Monitoring, Autonomous Rover, IoT, Environmental Sensors, Computer Vision, Rescue Robotics.

I. INTRODUCTION

Big disasters like earthquakes, landslides, fires and industrial accidents create bad environments that are dangerous for the people who are trying to help. In these situations it is very important to get information about what's happening so that we can plan how to help safely and effectively.

New technologies like robotics, special controllers and sensors have made it possible to make robots that can work safely in bad environments.

Robots that are made for disasters are designed to go into places that not safe for people collect information about the environment and send back pictures and videos to the people who are trying to help.

The robot we made has sensors that can detect things that are in the way and a camera that can show us what is happening in real time. The information from the sensors and the camera is sent to a system where the people who are trying to help can see what is happening and make decisions.

.

Disaster response robots are built to investigate unsafe locations, gather environmental information, and send visual feedback to rescue teams while minimizing human exposure to danger.

In addition, the rover includes ultrasonic sensors for obstacle detection and a camera module for real-time visual monitoring. The collected sensor data and video feed are transmitted wireless to a remote monitoring system where rescue personnel can analyze the situation.

Some researchers have developed IoT-based monitoring systems that use wireless communication to transmit environmental data from sensors to remote monitoring stations. These systems provide real-time information and allow emergency responders to make informed decisions.

By combining IoT technology, robotics, and computer vision, the proposed system provides an efficient and cost-effective solution for monitoring hazardous environments and supporting disaster management operations.

Fig.1 types of natural disaster

II. PROPOSED SYSTEM METHODOLOGY

The ARISE system is developed to address several limitations found in traditional disaster monitoring approaches. The system uses a robotic rover equipped with sensors, a camera module, and wireless communication technology.

We made the ARISE system to address some problems with the ways of monitoring disasters. The system uses a robot that is equipped with sensors, a camera and special communication technology.

The robot is controlled by a controller and a computer that work together to collect information from sensors control the system and communicate with other devices. The sensors monitor the environment and the special sensors that can see how things are help the robot move around.

A camera is installed on the robot to take pictures and videos of the disaster area. This helps the people who are trying to help understand what is happening without having to go into the environment.

The robot sends the information from the sensors and the camera to a monitoring system. The people who are trying to help can see the information. Make good decisions about how to help.

.

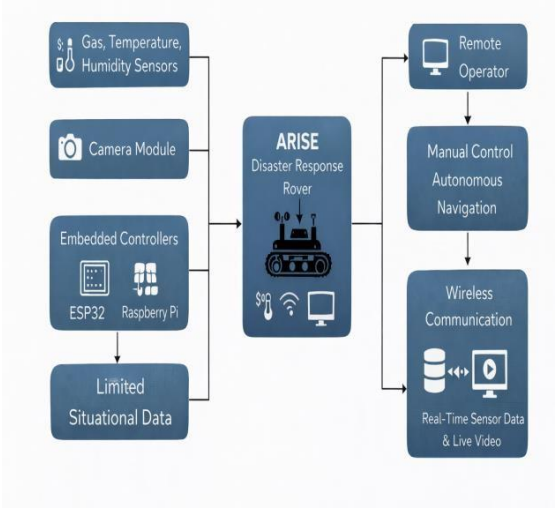

Fig.2 Block Diagram of Proposed Diagram

III. System Architecture Design and Simulation

The ARISE robot is made up of parts that work together to monitor the environment in disaster areas. The parts include the controller, computer, sensors, camera and special communication system. Each part does a job to make sure the robot works well.

The controller is the part that collects information from the sensors and sends it to the monitoring system. The computer is used to control the camera and do processing tasks. The camera takes pictures and videos of the disaster area, which helps the people who are trying to help understand what is happening.

The special sensors that can see how things are help the robot detect things that are in the way and measure distances. The robots movement system is made up of motors and a motor driver, which give the robot the power and control it needs to move around.

Fig.3 Existing system Architecture diagram

The robots circuit design is made up of parts that are connected together. The controller is the part that manages all the other parts.

The motor driver is connected to the controller to control the motors that make the robot move. The driver gets control signals from the controller. Gives the motors the power they need.

The sensors are connected to the controller to monitor the environment. The camera is connected to the controller to take pictures and videos. The information from the camera is sent to the monitoring system through communication.

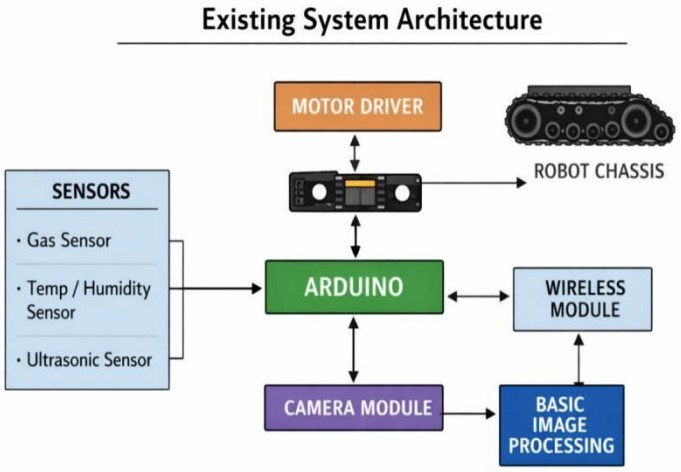

Fig.3 Existing system Architecture diagram

The circuit design of the rover consists of several interconnected modules. The microcontroller acts as the main controller and manages all the connected components.

The motor driver is connected to the mirocontroller to control the DC motors that drive the wheels of the rover. The driver receives control signals from the microcontroller and supplies the required current to the motors.

The sensors such as temperature sensors and gas sensors are connected to the input pins of the. These sensors continuously monitor the surrounding conditions and send real-time data to the microcontroller.

The camera module is connected to the for capturing images and live video. This information is transmitted through Wi-Fi to the monitoring system. A power supply unit, usually a rechargeable battery, provides power to the motor driver, and other components.

IV. System Prototype Development and Testing

We made a working prototype of the ARISE robot to show how it works in an environment. The prototype has parts, including the controller, motor driver, motors, sensors and camera.

The robots body is made to move across different surfaces. The motors are connected to the wheels. Controlled by the motor driver, which gets signals from the controller.

The sensors are installed on the robot to monitor the environment. The camera is used to take pictures and videos of the disaster area.

The robot sends the information from the sensors and the camera to the monitoring system. The people who are trying to help can see the information. Make good decisions about how to help.

These sensors continuously collect environmental data and send it to the microcontroller for processing. A camera module was also integrated into the system to capture live video of the surrounding environment.

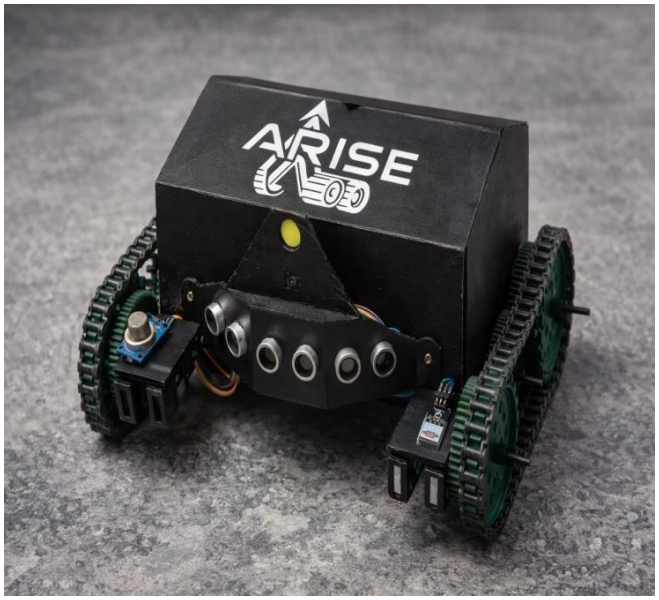

Fig.5 Hardware View

There are many other things inside; for example, neatly stacked equipment.

The system operates through a rechargeable battery which provides 12 volts to power both its motors and spray pump, while a DC-DC buck converter reduces the voltage to 5 volts for operation of sensors.

The system maintains operational efficiency because we separate power lines to prevent electrical noise interference.

During testing, the rover successfully navigated through simulated disaster environments and transmitted sensor data along with video feed to the monitoring device.

The experimental results indicate that the rover is capable of performing multiple tasks required in disaster rescue operations. During testing, the rover successfully navigated through simulated disaster environments and transmitted sensor data along with video feed to the monitoring device.

For example when the sensor detects something the system sends an alert to the monitoring system. The motor control signals can be tested to make sure the robot moves correctly.

Fig.6 Display

Before hardware implementation, the system can be simulated using software tools to verify its functionality. Simulation helps identify design issues and ensures that the system operates correctly.

The system works using a battery that gives the robot the power it needs. The battery gives 12 volts to the motors and other parts and a special converter reduces the voltage to 5 volts for the controller and sensors.

The system is designed to work and not have any problems with the power. During testing the robot moved around a simulated disaster environment. Sent information to the monitoring system.

The results of the testing show that the robot can do tasks that are needed in disaster rescue operations.

V. System Performance and Result Analysis

We tested the ARISE robot to see how well it works and to make sure it can help in disaster situations. The testing was done in a simulated disaster environment with obstacles and uneven surfaces.

The robot moved around. Sent information to the monitoring system. The sensors worked well. Detected changes in the environment. The camera took pictures and videos of the disaster area, which helped the people who are trying to help understand what is happening.

The results of the testing show that the robot works well and can help in disaster situations. The integration of sensing, communication and movement features makes the system a good tool, for disaster monitoring and rescue operations.

The ARISE rover is really good at helping out in disaster situations. It can move around. Sense things and send information back to people. This is helpful for rescue teams who need to know what is going on in a place that's hard to get to.

The ARISE rover can go into places that're not safe for people and send back pictures and information about the air and temperature. This helps the rescue teams know what they are up against and makes it easier for them to do their job.

The people who made the ARISE rover tested it. It worked really well. It can move around. Sense things and send information back to people. The rover has a computer called the ESP32 microcontroller that helps it do all these things.

The ARISE rover is good at detecting changes in the air and temperature. It can also take pictures. Send them back to people. This is really helpful for rescue teams who need to know what is going on in a place.

The ARISE rover is a tool for helping people in disaster situations. It can go into places that are not safe for people and send back information. This makes it easier for rescue teams to do their job and helps keep people safe.

In the future the ARISE rover could be even better if it had some features. For example it could have sensors that can detect obstacles. It could also have a way of sending information back to people.

The ARISE rover is an example of how technology can be used to help people in disaster situations. There are other examples of this too. For example there are robots that can go into buildings that are not safe and send back pictures and information.

VI. Conclusion

The ARISE Disaster Recovery Rover was designed and help rescue teams during disaster situations such as earthquakes, floods, and building collapses.

From the experimental testing, the rover demonstrated reliable performance in terms of mobility, sensing capability, and communication. The microcontroller successfully controlled the overall operation of the system and processed the data received from different sensors.

The environmental sensors were able to detect changes in temperature and gas levels, which are important indicators of dangerous conditions in disaster areas. In addition, the camera module provided live visual feedback, allowing operators to monitor the surroundings and guide the rover remotely.

The results show that the proposed system can be a useful tool in disaster management by helping rescue teams explore unsafe locations without risking human life. The rover can collect environmental data, transmit real-time information, and assist in locating trapped victims. This makes it a valuable technological solution for improving the efficiency of rescue operations.

In future work, the system can be further enhanced by adding advanced features such as obstacle detection using ultrasonic or sensors, improved communication range using long-distance modules, and artificial intelligence for automatic detection.

***Abstract*— Crop diseases, shifting environmental conditions, and Labor shortages are some of the major issues facing the modern agriculture industry. Manual inspections are the foundation of traditional field monitoring techniques, which are ineffective for identifying crop diseases early on. In order to monitor fields in real-time and automatically identify crop diseases, this paper describes the design and implementation of an IoT-based smart agricultural rover. The ESP32 microcontroller serves as the CPU for the system's intelligent agricultural rover. It makes use of PIR sensors for field surveillance, soil moisture sensors for irrigation, and a DHT11 sensor for environmental monitoring. The plants are photographed by the ESP32 camera module, and diseases are identified by a machine learning algorithm. Furthermore, relay modules use disease detection and sensor values to spray pesticides in the field. By enabling early plant disease detection and increasing overall field efficiency, this system provides a scalable solution for agriculture.**

KEYWORDS — IOT, DISEASE DETECTION, AUTONOMOUS AGRICULTURAL ROVERS, SMART IRRIGATION, CROP HEALTH, REAL-TIME MONITORING, IMAGE PROCESSING, AND PRECISION FARMING.

I. INTRODUCTION

Agriculture is an essential factor in the sustenance of the world's population. Nevertheless, modern agriculture is facing new challenges due to climate changes, scarcity of the labor force, and the rapid spread of plant diseases.

Traditional methods involve observing and inspecting the fields, which is a slow process and ineffective in early detection of plant diseases in the fields.With the advent of smart technology, precision agriculture has come up as an alternative solution to improve agricultural productivity and optimization.

Internet of Things (IoT) technology can monitor environmental and crop conditions by using multiple sensors and imaging technology.

However, most of the smart agriculture systems are based on stationary sensors that collect observational data, but do not support immediate action.

To overcome the shortcomings of the traditional systems, this work proposes a mobile smart agriculture rover that can perform real-time monitoring, analysis, and immediate action.

The proposed solution provides a comprehensive solution that includes environmental sensors, image-based plant diseases, and response systems. The inclusion of smart technology in the smart agriculture rover enhances the effectiveness of the solution by enabling immediate action.

Fig. 1. Overview of Smart Agricultural Monitoring Concept

The proposed solution not only improves the effectiveness of plant disease detection but also reduces the need for constant observation and inspection of the fields

II. PROPOSED SYSTEM METHODOLOGY

The proposed system has been designed for an autonomous agricultural rover that can be used for continuous monitoring, decision-making, and execution.

This system can be considered different from the conventional monitoring systems that only act as data collectors. This system can assess the conditions and react accordingly if any abnormal conditions are detected.

The rover can execute the operations through a cyclic process, which includes sensing, analysis, and response.

While the rover moves through the farm, it can collect information regarding the environmental conditions, such as moisture, temperature, and humidity, through the sensors.

At the same time, the ESP32-CAM sensor can collect information regarding the leaves of the crops, which can be used for the detection of diseases.

Based on the results obtained, the system can react accordingly. If the moisture level is less than the specified limit, the irrigation mechanism can be activated.

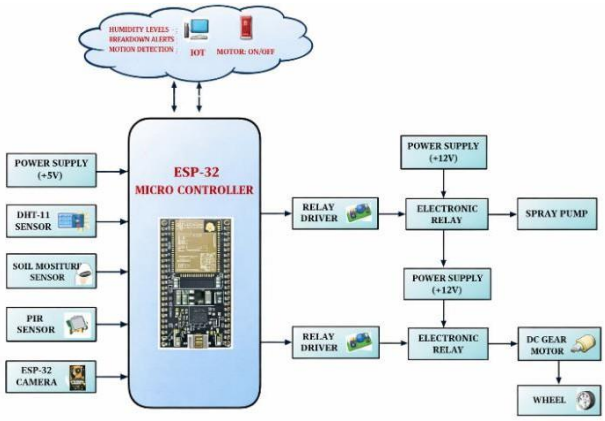

Fig. 2. Block Diagram of Proposed Diagram

III. SYSTEM ARCHITECTURAL DESIGN AND SIMULATION

The AI-powered Smart Agricultural Rover packs everything you need for today's precision farming. The system consists of separate modules which connect various functions including embedded controls and environmental sensors and computer vision and wireless communication and automated operations through a single autonomous platform.

The entire system delivers dependable performance with the ability to expand its capacity while consuming less power and maintaining operational speed that matches actual field work requirements.

The explanation comes in this way. The rover operates through its essential system components which include power management and sensing and processing and intelligence and communication and mobility and actuation. The system components operate independently to execute their specific tasks but they connect with each other to provide the rover with fast and smooth responses to external events.

Power serves as the fundamental base. The rover operates using a 12V battery pack which can be recharged and provides sufficient power for its DC motors and pumps. The buck converter reduces the input voltage to 5V which powers the ESP32 microcontroller and lighter sensors before converting it again to 3.3V for the logic circuits. The step-down system protects delicate components from power disturbances and voltage spikes, which ensures the system maintains stable operation.

Next, sensing. The rover tracks soil moisture and temperature and humidity levels which determine whether crops will thrive or fail. The system uses soil sensors to detect dry areas which become visible to plants only when they begin to suffer.

The system uses temperature and humidity data to determine plant health status while identifying potential disease outbreaks.

An ESP32-CAM system operates continuously to capture high-resolution leaf images which show yellowing and spots and abnormal leaf shapes that indicate developing problems.

The rover creates an extensive real-time assessment of crop health by combining information from sensors with visual data.

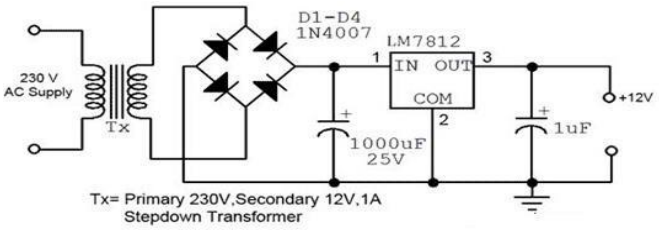

Fig. 3. Circuit Diagram of Regulated Power supply

The ESP32 microcontroller serves as the central processing unit for the system. The system assesses all incoming data according to established agronomic threshold standards.

The system instantly detects all system changes that occur during low moisture conditions or when weather patterns experience sudden shifts.

The system analyzes leaf images by using lightweight artificial intelligence models which operate like small convolutional neural networks to identify any problems.

The artificial intelligence system processes images to select specific features while marking any detected irregularities.

The rover uses actual sensor information together with advanced visual assessment technology to improve its decision-making process and prevent errors.

The system achieves smooth communication. The ESP32 Wi-Fi system establishes a connection between the rover and the cloud dashboard which transmits sensor data together with analytics and movement information and actuator status updates in real time.

The system records the exact time of each packet transmission which allows users to track the complete timeline of events. The IoT system transforms the rover into a smart node for the larger farm network which enables users to monitor and manage operations from any location.

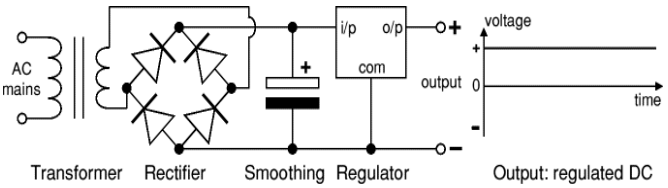

Fig. 4. Rectifier Circuit Diagram and Waveform

DC gear motors provide the robot's mobility while an H-bridge driver controls their movement. The rover moves forward and backward while it turns according to its commands.

The ESP32 uses PWM signals to control the speed of the system. The system uses relays to activate pumps and

sprayers for irrigation and pesticide spraying when it needs to operate. The system operates in a closed loop because the rover activates to handle issues after sensors detect a problem.

The team conducted multiple simulations to find and fix all system problems before they deployed the system to the field. The system began irrigation operations whenever soil moisture levels fell below preset thresholds while the AI successfully analyzed plant health through image processing.

The pre-testing process proved successful because it confirmed the rover would function correctly during actual outdoor operation.

IV. SYSTEM PROTOTYPE DEVELOPMENT AND TESTING

A new AI-based "Smart Agricultural Rover" has been designed to function as a small, mobile unit for real-time crop management.

Everything fits together—frame, electronics, sensors, comms, moving parts—into one solid unit.

Our team established their design goals when we started the project which required them to create a system that could operate as separate components while maintaining high energy efficiency and exceptional durability and easy maintenance.

The chassis needs to support all components which include the battery and ESP32 controller and motor driver and relay circuits and water tank and spray pump and all the sensors.

We selected DC gear motors which provide sufficient torque to operate in challenging agricultural environments.

The system connects to an H-bridge driver which enables us to control the rover's movement and speed through PWM signals generated by the ESP32.

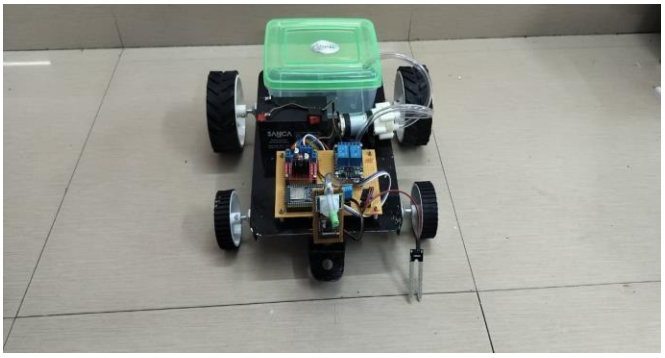

Fig. 5. Hardware View

There are many other things inside; for example, neatly stacked equipment.

The system operates through a rechargeable battery which provides 12 volts to power both its motors and spray pump, while a DC-DC buck converter reduces the voltage to 5 volts for operation of ESP32 and sensors.

The system maintains operational efficiency because we separate power lines to prevent electrical noise interference.

We installed three sensors to monitor environmental conditions through a soil moisture sensor which measures root water content and a temperature-humidity sensor which tracks environmental conditions and an ESP32-CAM which provides visual inspections of the crops.

The sensors data is read by our custom firmware which we developed for the ESP32 to control all system operations through decision making while transmitting data and managing motor and pump functions.

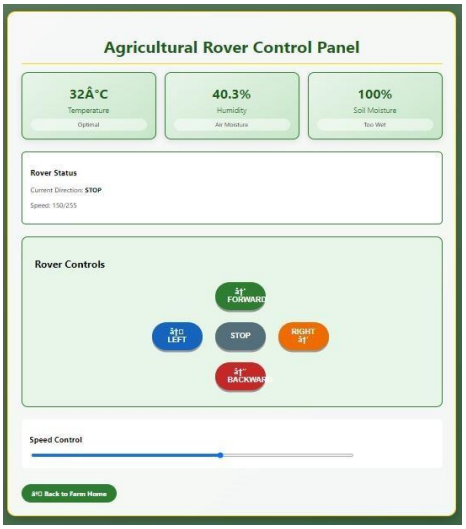

Fig. 6. IOT Display 1

The code runs both in a loop and by interrupts, so the rover can keep an eye on everything and still react fast. We established threshold levels which activate the rover's watering system when soil moisture reaches an extreme dry condition.

For crop monitoring, we built in basic image processing to spot odd colors or textures that could mean disease. The rover transmits all data through a wireless connection to a cloud dashboard using Wi-Fi.

Fig. 7. IOT Display

The testing process followed a sequential approach which began with testing each individual component, namely the sensors, motors, relays, and comms modules. The soil sensor calibration process involved testing the sensor under various water levels while we verified the environmental sensor performance by comparing it to standard equipment and we assessed the motors ability to operate under different speed and directional operations and various weight loads. We tested the spray pump to verify its ability to activate at the correct time while distributing water in an even manner throughout the area.

Next, we ran the complete system. We adjusted soil moisture levels to test whether the rover would automatically irrigate the crops. We demonstrated both healthy and diseased leaves to test whether it could detect problems and apply pesticide at the correct time. We established that the IoT dashboard received real-time data updates while maintaining Wi-Fi connectivity. We conducted extended system tests to verify its reliability by testing for potential system failures.

The rover established effective power management together with precise environmental detection and quick response capabilities and dependable data transmission and automatic system activation at appropriate times. The system maintained continuous surveillance over the agricultural fields yet it operated as an active system that responded to critical situations. The complete functionality of the system demonstrates that Internet of Things devices together with intelligent control systems and automated processes are compatible with portable agricultural robots. The prototype demonstrates that this method achieves success in actual agricultural environments while it establishes a foundation for future developments which include GPS technology and obstacle detection systems and advanced machine learning capabilities.

V. System Performance and Result Analysis

We conducted a thorough evaluation of the AI-driven Smart Agricultural Rover to determine whether its performance matched its advertised capabilities during our field tests. We wanted answers:Can you count on it How fast does it react Does it really sense what is happening around it while maintaining communication and performing tasks without errors. We investigated all aspects of the system including its environmental monitoring capabilities and plant disease detection speed and actuator performance and movement efficiency and system stability during simultaneous operation of all components.

We checked the environmental sensors by comparing the rover readings with standard reference tools. The soil moisture sensor operated continuously without interruption. The water level change made the sensor show immediate results. The rover system detected dry soil conditions therefore it activated the irrigation system with no delay between systems. The temperature and humidity sensors maintained accurate readings during stable weather conditions except for the typical minor fluctuations that usually occur. The system detected all out-of-range readings and activated automatic response measures because the automation system operated successfully.

Next up: disease detection. The rover received two types of leaves which included healthy specimens and diseased samples. The camera and onboard image analysis detected all visible problems through its ability to identify changes in color and texture. The built-in logic could tell a normal leaf from a sick one and fired up the pesticide sprayer when needed. The time between taking a photo and starting the spraying process remained brief enough for actual agricultural operations therefore the ESP32 image processing system functioned effectively.

The rover's mobility performance needed to be evaluated through our testing. The testing involved driving the rover across both flat surfaces and areas with minimal surface roughness. The DC gear motors used pulse-width modulation control to maintain both speed and path direction. The system executed movement commands for forward and backward motion and turning operations without any complications. The power system maintained continuous operation during simultaneous motor and sensor activity because it experienced no voltage drops or operational interruptions.

We watched the rover transmit its data through Wi-Fi to the IoT dashboard system. The system displayed all sensor readings together with updates and actuator status information in real time to the cloud. The connection maintained its stability throughout the standard wireless operating distance. The tests showed that all data remained complete because packet checks confirmed no losses or missing segments.

The team established operational scenarios which would activate the system for automated testing. The irrigation system activated immediately when we dried out the soil to restore moisture levels. The pesticide sprayer activated after we applied disease indicators to the leaves. The entire system transitioned from detection to operational mode without any requirement for human assistance. The system operates as a complete closed-loop design.

The prototype functions as a dependable smart farming tool which operates at high efficiency while maintaining quick response times. The system combines environmental sensing technology with onboard processing capabilities and wireless communication systems and automated systems to provide precise monitoring and immediate operational response. The system enables easier crop monitoring operations while reducing manual labor requirements and conserving both water and pesticide resources and establishing a foundation for future development of scalable precision agriculture technologies.

VI. CONCLUSION

The paper outlined the design and implementation of an intelligent agricultural rover that is capable of conducting automatic crop monitoring and management of diseases using IoT and embedded systems technologies. The suggested system utilizes environmental and image sensing to monitor crops continuously and detect any possible irregularities that may be associated with diseases in crops. The use of environmental and image sensing in crop monitoring ensures that there is a deeper understanding of

environmental conditions, thus enabling the detection of any possible irregularities that may be associated with diseases in crops.

The suggested system is beneficial in that it is capable of operating autonomously in the agricultural environment. The ability of the suggested system to operate autonomously in the agricultural environment ensures that it is capable of providing automatic responses to any unfavorable environmental conditions in real-time without human intervention.

For instance, when irregularities in soil moisture are detected by the suggested system, it is capable of activating the irrigation systems to provide solutions to the problem of dry soil. Additionally, when irregularities associated with diseases in crops are detected by the suggested system, it is capable of activating pesticide sprayers to provide solutions to the problem of diseases in crops.

According to these experimental results, it is observed that the system works effectively in environmental monitoring, disease detection, and actuation. The sensors are working effectively in providing environmental data, and the data transmission between different components of the system is also working effectively.

Moreover, it is observed that the rover works effectively in providing stability in the agricultural environment.

Overall, it is observed that the proposed solution is beneficial in advancing the field of smart agriculture by providing accurate monitoring, detecting diseases, and performing actuation effectively. These are beneficial in reducing costs, increasing crop production, and maintaining sustainable agriculture by optimizing the use of water and chemical resources.

In order to improve the proposed solution, it is suggested to use advanced navigation systems such as GPS for accurate field mapping, obstacle detection for effective movement of the rover, and advanced machine learning algorithms for accurate classification of diseases in crops. These are beneficial in advancing the proposed solution to be used in modern precision farming scenarios

***Abstract*—**The Smart Blind Shoe is an assistive device designed to help visually impaired people walk safely and independently. It uses ultrasonic sensors to detect obstacles and alerts the user through vibration or sound signals. A microcontroller processes the sensor data in real time, improving navigation and safety. Similar concepts have been developed in research works using technologies like ultrasonic sensors, IoT, GPS, and AI for better accuracy. The main aim of this project is to create a simple, low-cost, and user-friendly design. Compared to earlier systems, this model focuses on affordability, portability, and ease of use while still providing effective obstacle detection

Keywords— Smart Shoe, Assistive Technology, Obstacle Detection, Real-Time Navigation, Visually Impaired, Embedded Systems, Wearable Technology, Ultrasonic Sensors, Mobility Assistance

I. INTRODUCTION

Visual impairment is one of the most common disabilities worldwide, affecting millions of individuals of all ages. According to the World Health Organization (WHO), approximately 285 million people globally are visually impaired, and about 39 million are completely blind. Navigating everyday environments poses significant challenges for these individuals. Common obstacles include uneven surfaces, stairs, street crossings, and unexpected objects in their path. Such challenges limit their independence, restrict social interactions, and reduce overall quality of life.

Traditional mobility aids, such as canes and guide dogs, help in detecting obstacles, but they have limitations. Canes only detect obstacles at the ground level, leaving overhead or mid-level objects undetected. Guide dogs require training and maintenance, which may not be feasible for everyone. Therefore, there is a pressing need for modern, technology-based solutions that are affordable, reliable, and user-friendly.

Visually impaired individuals face difficulties in independently navigating unfamiliar or crowded environments. Accidental collisions with obstacles can cause injuries, reduce confidence, and limit mobility. Existing aids do not provide comprehensive real-time feedback for all types of obstacles, leaving gaps in safety and efficiency. There is a clear need for an assistive device that can continuously monitor the surroundings and alert users about obstacles in a timely manner.

The motivation behind developing a Smart Shoe for blind individuals arises from the need to enhance independence and safety for visually impaired people. By leveraging modern sensor technology and microcontroller programming, it is possible to develop a wearable device that automatically detects obstacles and alerts the user.

Arduino-based smart shoes are attractive because of their low cost, portability, and versatility. They can be programmed to provide real-time feedback via vibration or sound, alerting the user without interrupting their walking. This allows visually impaired individuals to move more confidently, safely, and efficiently in different environments, including homes, offices, streets, and public spaces.

II. LITERATURE SURVEY AND RELATED WORK

The work by Teja Chava et al. highlights some limitations in the smart shoe system. The system also consumes more power, reducing battery life. It depends on internet connectivity, which may not always be available. The design increases cost and complexity, and ensuring comfort for daily use remains a challenge [1].

The work by N. Sohan et al. highlights some challenges in smart assistive shoes. The system may have limited obstacle detection accuracy and slight delays in response. It also increases system complexity and cost due to multiple components. Ensuring comfort and lightweight design remains difficult [2].

The work by Iuliana Chiuchisan et al. has some limitations in obstacle detection accuracy. The system depends on sensors that may be affected by surroundings. It also consumes more power, reducing battery life. Additionally, ensuring comfort and easy daily use is challenging [3].

The work by Qianli Xu et al. highlights some limitations in vibrating footwear systems. The vibration feedback may not always be clearly understood by users. The system can have limited accuracy in complex environments. It may also require

user training for effective use. Power consumption and comfort remain important challenges [4].

The work by Vijayaraja Loganathan et al. has some limitations in the smart shoe system. The design becomes complex because of multiple features. It can increase cost and power consumption. Also, ensuring comfort and easy use is challenging [5].

The work by Azadeh Kian et al. has some limitations in wearable systems. The design is complex and may be costly. It also requires high power for operation. Additionally, ensuring comfort and ease of use for daily wear is challenging [6].

The work by Shering Tenji Sherpa and Akinori Kimura has some limitations in detection systems. The system may have accuracy issues in identifying signals and obstacles. It can also be affected by environmental conditions like lighting. The design may increase complexity and power usage. Additionally, ensuring reliable real-time performance remains a challenge [7].

The work by Jeffrey Chehade et al. has some limitations in smart shoe systems. The design can be complex due to multiple components. It may also increase cost and power consumption. The system can face challenges in accurate obstacle detection. Additionally, ensuring comfort and reliability for daily use remains difficult [8].

The work by Pratik Bhongade et al. has some limitations in IoT-based smart shoes. The system depends on internet connectivity, which may not always be reliable. It can also consume more power due to IoT components. The design may increase complexity and cost. Additionally, ensuring comfort and ease of use is challenging [9].

The work by T. S. Aravinth highlights some limitations in the smart guiding system. The system depends on WiFi and Bluetooth, which may not always be reliable. It can also consume more power due to wireless communication. The design may increase complexity and cost. Additionally, ensuring real-time response and ease of use is challenging [10].

III. SYSTEM DESIGN

The system design of the Smart Shoe project focuses on creating a wearable device that can detect obstacles in real-time and alert the user in fig 1, enhancing mobility and safety for visually impaired individuals. The design integrates hardware components such as sensors, microcontroller, and feedback devices with software programmed on Arduino to control and process sensor data.

A. Components of the system

The system can be divided into the following main components:
1. Ultrasonic Sensors
Detect obstacles in the user's path by measuring the distance between the shoe and nearby objects. Continuously send distance data to the microcontroller.
2. Arduino Microcontroller
Acts as the brain of the system.
Processes data from the sensors to determine if an obstacle is within a predefined safe range.
3. Feedback Devices (Vibration Motors / Buzzer)
Provides immediate alerts to the user if an obstacle is detected.
Vibration motors are embedded in the shoe for tactile feedback; a buzzer provides audio alerts.

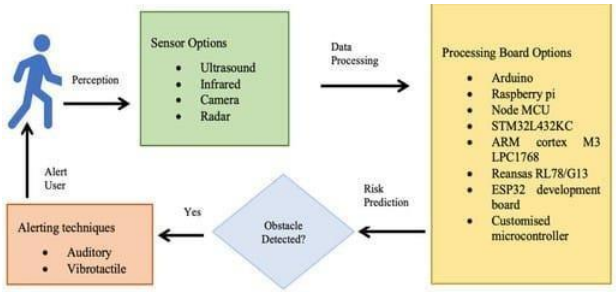

Fig.1 Systematic working of model

B. ***Working principle***
1. The ultrasonic sensor continuously emits sound waves and fig 2 measures the time taken for the echo to return.
2. Arduino calculates the distance using the formula:
Distance=Time/Speed
3. If the distance is less than the safe threshold, Arduino activates the vibration motor or buzzer to alert the user.
4. The system continuously updates the readings to provide real-time feedback

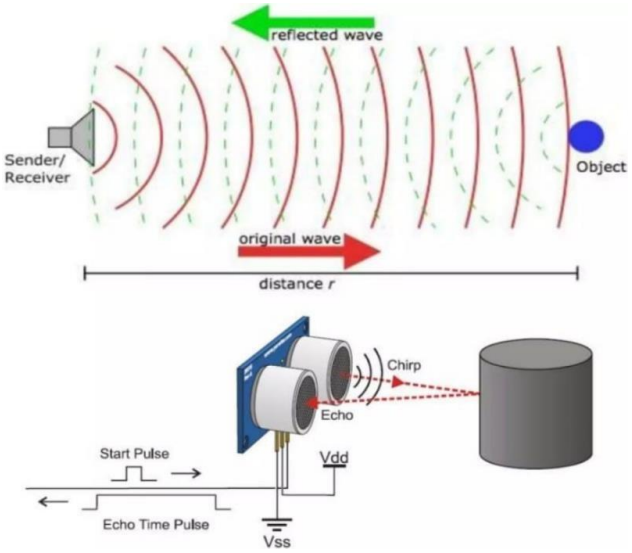

Fig.2 Working mechanism of Ultrasonic sensor

C. ***Feature of the design***
Portable and wearable: All components are integrated into a shoe.
Real-time obstacle detection: Continuous monitoring and immediate alert system.
Low-cost and easy to assemble: Uses widely available components like Arduino and ultrasonic sensors.
Hands-free operation: Alerts user automatically without manual intervention.

IV. HARDWARE COMPONENTS

A. *Arduino Microcontroller*
Acts as the central processing unit of the system. signals from the ultrasonic sensors and triggers feedback devices.
Arduino Uno is commonly used due to its low cost, simplicity, and versatility.

B. *Ultrasonic Sensors (HC-SR04)*
Measure the distance between the shoe and obstacles by emitting ultrasonic waves and calculating the time taken for the echo to return.
Provide real-time distance data to the Arduino.
Can detect obstacles both at ground level and slightly above.

C. Feedback Device

1. vibration motors

Embedded in the shoe to provide tactile alerts to the user.
Vibrate when obstacles are detected within a predefined distance.

2. Buzzer

Provides auditory alerts for obstacle detection.
Works in combination with vibration motors for better feedback.

D. Power Supply

Provides electricity to the Arduino, sensors, and feedback devices.
Usually a rechargeable battery is used to ensure portability.

E. Jumper Wires and Breadboard:

Jumper Wires and Breadboard: For easy circuit connections.
Resistors (if needed): To control current for certain components
Shoe Base: Integrates all components into a wearable form.

V. METHODOLOGY

The proposed Smart Blind Shoe is developed to assist visually impaired individuals in navigating their surroundings safely by detecting obstacles using ultrasonic sensing technology. The system is designed to provide real-time feedback through vibration or sound alerts, enabling users to move independently without relying on visual cues.

1. System Design and Component Selection

The system consists of key components such as an ultrasonic sensor, microcontroller (Arduino), buzzer or vibration motor, and a power supply unit. The ultrasonic sensor is responsible for obstacle detection, while the microcontroller processes the received data and controls the alert system. All components are chosen to ensure low cost, compact size, and energy efficiency for wearable use.

2. Placement of Sensors

The ultrasonic sensor is strategically mounted on the front portion of the shoe to detect obstacles in the walking path. This placement ensures that objects such as walls, steps, or barriers are identified before the user reaches them. In some designs, multiple sensors can be used to cover different directions for better accuracy.

3. Working Principle (Ultrasonic Sensing)

The system operates based on the time-of-flight principle. The ultrasonic sensor emits high-frequency sound waves (above human hearing range). When these waves encounter an object, they are reflected back to the sensor fig 3.
The time taken for the echo to return is measured by the microcontroller. Using this time, the distance to the obstacle is calculated using the formula:

Distance = (Speed*Time)/2

This calculation is continuously performed to monitor the surroundings in real time.

4. Data Processing and Decision Making

The microcontroller processes the measured distance and compares it with predefined threshold values. These thresholds are set based on safe walking distances.
If the distance is greater than the safe limit, no alert is given.
If the distance is within the warning range, a mild alert is triggered.
If the distance is very close, a strong or continuous alert is activated.

5. Alert Mechanism

The system uses either a buzzer (audio alert) or a vibration motor (haptic feedback) to notify the user.
Buzzer: Produces sound signals with varying frequency.
Vibration motor: Produces vibrations with varying intensity.
For better usability, vibration is often preferred as it does not disturb others and is easy for the user to interpret.

6. Power Supply and Integration

The entire system is powered by a rechargeable battery, making it portable and suitable for daily use. All components are compactly integrated into the shoe structure to ensure comfort and durability.

7. Real-Time Operation

The system works continuously in a loop:
Emit ultrasonic waves
Receive echo signal
Calculate distance
Compare with threshold
Trigger alert if needed
This loop ensures real-time obstacle detection and immediate feedback.

8. Safety and Efficiency Considerations

The design ensures:
Low power consumption
Lightweight structure
Quick response time
Reliable performance in different environments
The system is tested under various conditions to ensure accuracy and user safety.

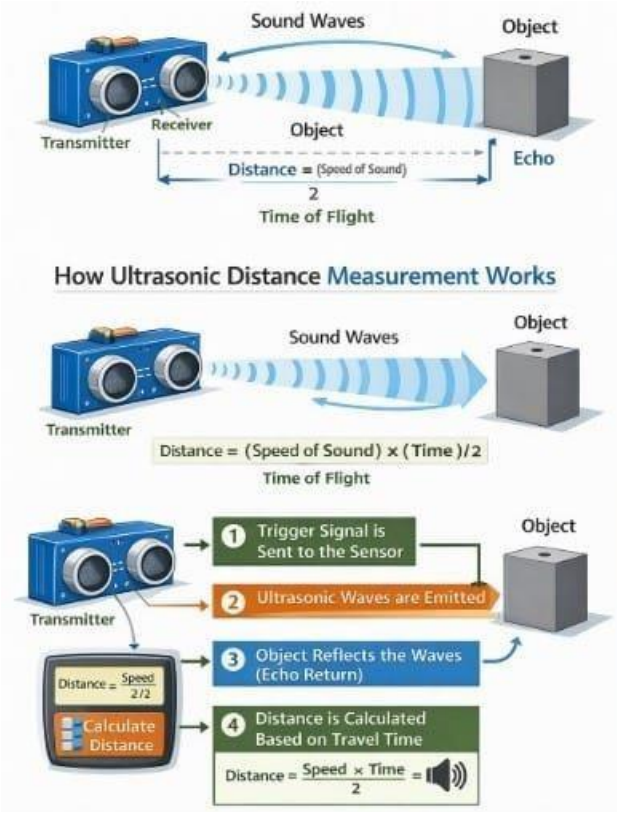

Fig.3 Operational representation of smart shoe

VI. PERFORMANCE ANALYSIS

1. Accuracy of Obstacle Detection

The accuracy of the smart blind shoe depends on how precisely the ultrasonic sensor measures the distance to obstacles. Table 1

shows the accuracy of obstacle detection. The system performs best in short to medium ranges, which are most important for walking. However, factors like soft materials, irregular surfaces, and object angles can slightly affect the accuracy because ultrasonic waves may get absorbed or scattered.

Table 1. Accuracy of obstacle detection

Factor	Performance
Distance range	0.1m-2m
Hard Surfaces	Very accurate detection
Soft Surfaces	Slight reduction in accuracy
Angled Objects	Minor measurements errors

2. Response Time

Response time refers to how quickly the system detects an obstacle and alerts the user. Table 2 shows the response time taken of the smart shoe. The smart blind shoe works in real-time by continuously sending and receiving ultrasonic signals. The delay between detection and alert is very small, allowing the user to react quickly and avoid obstacles safely.

Table 2. Response time taken of the smart shoe

Parameter	Performance
Detection Speed	Very fast
Alert Delay	Less than 1 second
Real time Operation	Continuous monitoring
User Safety	High due to quick response

3. Detection Range and Coverage

The detection range defines how far the sensor can identify obstacles, while coverage refers to the area it can monitor. The smart blind shoe is optimized for a range suitable for walking. Table 3 shows the coverage of the smart shoe. However, since a single sensor is used, it mainly detects obstacles in the front direction, and side obstacles may not be detected effectively.

Table 3. Coverage of the smart shoe

Parameter	Performance
Minimum Range	~20cm
Maximum Range	~200cm
Direction Coverage	Forward only
Side Detection	Limited

4. Power Consumption

Power consumption is an important factor for wearable devices like the smart blind shoe. The system uses low-power components such as an ultrasonic sensor and microcontroller, making it energy efficient. Table 4 shows the power consumption of the smart shoe. This allows the device to operate for several hours on a single battery charge, ensuring convenience for daily use.

Table 4. Power Consumption of the smart shoe

Parameter	Performance
Power Usage	Low
Battery Type	Rechargeable
Operating time	Several hours
Efficiency	High

VII. COMPARISON WITH EXISTING SYSTEMS

Assistive technologies for visually impaired individuals have evolved over time, starting from simple tools like the traditional white cane to more advanced electronic navigation systems. The white cane is the most commonly used aid due to its simplicity, low cost, and reliability. It helps users detect obstacles through physical contact. However, it has several limitations, such as a very short detection range, inability to detect obstacles above waist level, and complete dependence on the user's skill and reaction time.

Some existing electronic systems use basic sensors or GPS-based navigation, but they are often bulky, expensive, or complex to operate. These systems may also suffer from delayed response, high power consumption, or lack of real-time feedback, making them less practical for everyday use.

The proposed Smart Blind Shoe system addresses these limitations by integrating ultrasonic sensing technology with a microcontroller and an efficient alert mechanism. Unlike traditional methods, it detects obstacles before physical contact using sound waves and provides immediate feedback through vibration or buzzer alerts. This improves the safety and confidence of the user while walking. Additionally, the smart blind shoe is designed to be lightweight, wearable, and easy to use without requiring continuous hand involvement. It operates automatically and provides real-time assistance, making it more user-friendly compared to existing systems. The use of low-power components ensures longer battery life, and the compact design makes it suitable for daily use. Table 5 shows the comparison of the proposed dual mode shoe with Existing Smart Shoe.

Overall, the proposed system offers a significant improvement in terms of detection capability, response time, user comfort, and technological advancement, making it a more efficient solution for visually impaired individuals.

Table 5. Comparison of the proposed dual mode shoe with Existing Smart Shoe

Feature / Criteria	Traditional shoe	Smart shoe (Existing)	Proposed Dual-Mode shoe
Basic Navigation Support	Yes	Yes	Yes
Obstacle Detection	Limited	Limited	Yes
Fall Detection	No	Partial	Yes (Multi-Parameter)
Water Support	No	No	Yes
Staircase Detection	No	Limited	Yes
IoT-Based Emergency Alert	No	Yes	Yes
Adaptive Sensitivity	No	No	Yes
Vibration Alerts	No	Yes	Yes
Multi-Sensor Fusion	No	Limited	Yes
Cost Efficiency	Low	Moderate	Affordable

VIII. RESULTS AND DISCUSSION

The Smart Blind Shoe was successfully designed and tested to evaluate its performance in real-world conditions. The system demonstrated effective obstacle detection, quick response, and reliable alert mechanisms, making it suitable for assisting visually impaired individuals.

ARDUINO CODE

```
// Smart Shoe for Blind People - Arduino Code
// Components: Arduino Uno, HC-SR04 Ultrasonic Sensor, Vibration Motor/Buzzer
// Pin Definitions
const int trigPin = 9; pin      // Ultrasonic sensor TRIG
const int echoPin = 10;      // Ultrasonic sensor ECHO pin
const int motorPin = 13;   // Vibration motor or buzzer
// Distance threshold (in centimeters)
const int safeDistance = 30; // Alert if obstacle is closer than 30 cm
pinMode(trigPin, OUTPUT);
pinMode(echoPin, INPUT);
pinMode(motorPin, OUTPUT);
// Initialize serial communication (optional, for debugging)
Serial.begin(9600);
}
void loop() {
long duration;
int distance;
// Send ultrasonic pulse
digitalWrite(trigPin, LOW);
delayMicroseconds(2);
digitalWrite(trigPin, HIGH);
delayMicroseconds(10);
digitalWrite(trigPin, LOW);
// Read echo
duration = pulseIn(echoPin, HIGH);
// Calculate distance (cm)
distance = duration * 0.034 / 2;
// Print distance for debugging
Serial.print("Distance: ");
Serial.print(distance);
Serial.println(" cm");
// Check if distance is below safe threshold
if(distance <= safeDistance){
digitalWrite(motorPin, HIGH); // Turn on vibration/buzzer
}
else {
digitalWrite(motorPin, LOW); // Turn off vibration/buzzer
}
delay(100); // Short delay for stability
}
```

During testing, the ultrasonic sensor accurately detected obstacles within the range of 20 cm to 200 cm. The system responded quickly by activating the vibration motor or buzzer whenever an obstacle was detected within the predefined threshold distance. The response time was observed to be less than 1 second, ensuring real-time feedback. The alert system worked effectively, with vibration intensity increasing as the obstacle distance decreased.

The system performed well in both indoor and outdoor environments, though slight variations were observed due to environmental factors. The battery performance was satisfactory, allowing several hours of continuous operation. The results confirm that the system can help users detect obstacles early and navigate safely without physical contact.Fig.4 shows the Performance evaluation of smart shoe

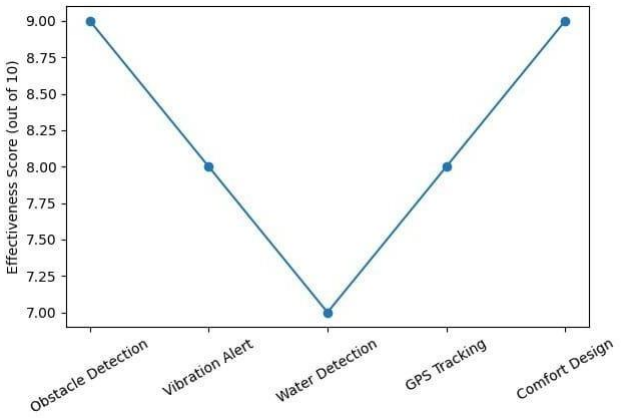

Fig.4 Performance evaluation of smart shoe

The results indicate that the Smart Blind Shoe is an effective assistive device with significant advantages over traditional systems. The use of ultrasonic sensors enables early obstacle detection, which improves user safety and confidence.The real-time response of the system ensures that users receive **immediate** alerts, allowing them to react quickly. The vibration-based feedback is particularly useful as it provides a non-intrusive and easily understandable signal.

However, some limitations were observed during testing: The system may have reduced accuracy with soft or irregular surfaces. Detection is mainly limited to the forward direction, as only one sensor is used. Environmental factors like temperature and noise can slightly affect performance.

Despite these limitations, the overall performance is satisfactory and meets the objective of assisting visually impaired individuals. Future improvements such as adding multiple sensors, GPS, or AI-based navigation can further enhance the system**.**

IX. CIRCUIT DIAGRAM OF THE PROPOSED SYSTEM

The circuit diagram of the blind shoe system is designed using an Arduino UNO as the central processing unit, which controls all input and output operations. An ultrasonic sensor (HC-SR04) is employed to detect obstacles by transmitting ultrasonic waves and receiving their echoes. The sensor is powered through the 5V and GND pins of the Arduino, while its TRIG and ECHO pins are connected to digital pins 10 and 9, respectively. By calculating the time taken for the echo to return, the Arduino determines the distance between the user and nearby objects. Fig.5 shows the circuit diagram of the proposed system.

Based on this distance measurement, the Arduino activates alert mechanisms to notify the user. A buzzer connected to digital pin 11 generates an audio warning, and an LED connected to pin 13 provides a visual indication. Both components are connected to ground to complete the circuit. The system can be programmed such that the frequency or intensity of the buzzer increases as the obstacle gets closer, offering a more effective and intuitive warning system

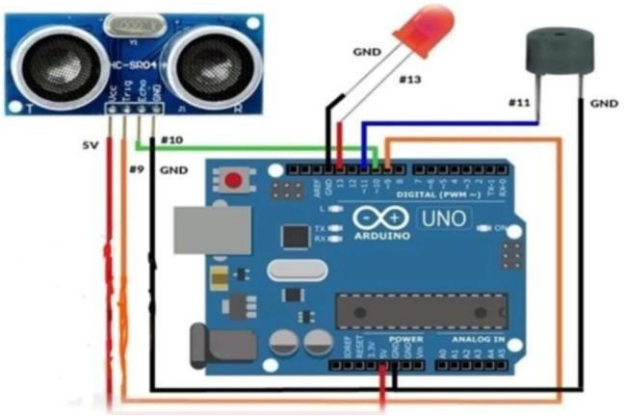

Fig.5 Circuit Diagram of the proposed system

X. ADVANTAGES AND APPLICATIONS

A. Advantages

1. Enhanced Mobility and Safety Helps visually impaired individuals navigate safely without relying entirely on others. Detects obstacles in real time, reducing the risk of accidents.

2. Low-Cost and Easy to Build Uses affordable components like Arduino and ultrasonic sensors, making it cost-effective for large-scale use.

3. Lightweight and Portable Design Compact integration into a shoe makes the device comfortable and easy to wear.

4. Real-Time Feedback Provides immediate alerts through vibration or buzzer, ensuring instant response to obstacles.

5. Customizable and Scalable Can be upgraded with additional features such as GPS, Bluetooth, or voice guidance.

6. Energy Efficient Consumes minimal power, allowing longer battery life for extended usage.

7. User-Friendly Operation Fully automatic — requires no buttons or complex setup, ideal for daily use.

B. Applications

1. Assistance for Visually Impaired People The primary application is to assist blind and visually impaired individuals in navigating independently.

2. Navigation Aid in Dark or Low-Visibility Areas Can help sighted people move safely in low-light conditions or smoky environments.

3. Use in Smart Wearable Technology A step toward smart wearable innovations in healthcare and safety applications.

4. Obstacle Detection Systems the same concept can be applied to robots or vehicles for autonomous obstacle detection.

5. Educational and Research Projects Useful for engineering students to learn about embedded systems, sensor integration, and assistive technology.

XI. FUTURE ENHANCEMENTS

The Smart Shoe project provides a low-cost, wearable, and real time obstacle detection system. However, there are several opportunities to improve and expand its functionality to make it more advanced, accurate, and user-friendly.

A. Integration with GPS and Navigation Systems

Incorporating GPS modules can help visually impaired users navigate unfamiliar outdoor environments. Turn-by-turn guidance can be provided through audio or vibration alerts, making the device a complete navigation aid.

B. Voice Assistance

Adding voice feedback can inform users about obstacles, directions, or nearby landmarks. Integration with text-to-speech modules can make navigation more intuitive.

A. AI-Based Obstacle Recognition

Using cameras and AI algorithms, the system can recognize moving obstacles, such as vehicles or people. This can enhance safety in crowded environments where ultrasonic sensors alone may not be sufficient.

B. Wireless Connectivity and Mobile App Integration

Integrating Bluetooth or Wi-Fi can allow users to connect the shoe to a smartphone app. Features like route planning, emergency alerts, and monitoring of battery status can be added.

C. Solar or Rechargeable Power Solutions

Using solar panels or efficient rechargeable batteries can increase device autonomy. Reduces dependence on frequent manual charging, improving convenience.

D. Lightweight and Modular Design

Future designs can further reduce weight and bulkiness. Modular components can allow easy replacement or upgrading of sensors, motors, or power supply.

E. Multi-Sensor Integration

Adding infrared sensors, gyroscopes, or accelerometers can provide better obstacle detection and gait analysis. Enables advanced features such as fall detection and terrain adaptation.

XII. CONCLUSION

The Smart Shoe for Blind People using Arduino successfully demonstrates how technology can improve the quality of life for visually impaired individuals. By integrating ultrasonic sensors, Arduino microcontroller, and feedback devices like vibration motors or buzzers, the system provides real-time obstacle detection and alerts the user immediately, ensuring safe and independent navigation.

This project highlights several important aspects: The system is wearable, portable, and user-friendly, allowing hands-free operation. It uses low-cost components, making it affordable and accessible for a wide range of users.
The project provides a foundation for future enhancements, such as GPS integration, voice assistance, AI-based obstacle recognition, and mobile connectivity.

In conclusion, the Smart Shoe is a practical, innovative, and socially impactful solution for visually impaired individuals. It not only enhances mobility, safety, and confidence but also demonstrates the potential of wearable assistive technologies in improving independence and daily life for differently-abled people.

ABSTRACT: The adoption of lightweight CNN model is used to detect plant diseases quickly and reliably using image-based learning technique. Crop losses caused by plant infections occur every year and significantly impact farmers' livelihoods. Traditional methods, such as inspecting the conditions of the plant by the agriculture officers, were time-consuming, expensive, and often inaccurate. It is really impractical for large-scale deployment. The proposed system applies ML and DL techniques to examine leaf images and identify diseases automatically. The model overcomes the generalization error and predicts the disease more accurately. The accuracy was 98.7, and the F1-score was 98.5. The Mean Squared Error was very low, approximately equivalent to 0.8.

Keywords: Mean Squared error,F1-score, robust, Generalization.

1. INTRODUCTION

The population of India has been increasing enormously, and the need to protect the crops is becoming a more crucial task than before. It is estimated that plant diseases pose a large yield loss annually, affecting up to 40% of the economy. If the world population increases similarly, the need for food will also increase exponentially. Therefore, the protectionof crops from various diseases becomes a basic need that ensures a continuous supply of food to all people and eradicates hunger and poverty.

In earlier practices, plant diseases were identified through manual observation by experts. Visual Inspection is effective only on a small scale, but it takes a lot of time and it is very costly when used on a broad scale. Since it is done manually, the detection is prone to human error. So, this app is designed with several features such as voice assistance and multilingual support, which enable even uneducated people to identify what disease has affected their crops and the corresponding treatments to be done. Along with deep learning, the use of CNN model ,analyzes images to detect diseases accurately and suggests suitable treatment options.This enables the application to perform much faster than human experts.

This paper presents a plant detection application utilizing deep learning, which enables the diseases automatically without manual intervention, providing solution instantly. The usage of Tensor Flow Lite compressed the model's size and made it efficient while deploying. The use of Google Colab, from downloading the dataset to preprocessing it (removing null values) and training the model, made the entire workflow transparent. The main goal of this app is to support

farmers by providing various diseases and promoting the Sustainable Development Goals.

2. LITERATURE REVIEW

Traditional Methods: These traditional methods mainly depend on human visual inspection by agricultural experts. They try to identify and predict diseases based on symptoms such as discoloration(change of color or degradation of color) and spots. It often shows errors and is inefficient for large-scale farms. More advanced traditional methods are accurate but time-consuming and cost- inefficient, which is not suitable for most farmers

Modern approaches: The modern approach mainly focuses on various techniques of machine learning and neural based networks.These methods automatically analyze images of plant leaves or other parts to identify and classify diseases.

Dataset: PlantVillage dataset is the most commonly used dataset (consists of nearly 54000 images across 38 classes in many distributions. The dataset most commonly contains controlled background, zoomed leaf photos. Field imagery from UAVs, multispectral datasets, and other locally collected small datasets.

Evaluation Metrics: The performance can be analyzed based on accuracy and recall. It tells how well the model identifies the true positives and false negatives.

Imaging: RGB imaging is the cheapest, easiest, and most widely used for visual symptom detection.

Multispectral/hyperspectral sensors capture wavelengths beyond visibility and enable early detection of diseases before visible symptoms appear, and can help to differentiate various types of pathogens. These sensors are very helpful in identifying diseases.

Early work used color/texture features (e.g., color histograms) + classifiers like SVM, Random Forest, k-NN. These methods can be interpretable but require careful feature design and do poorly under large visual variability (lighting, viewpoint, background). So we used CNN(convolutional neural networks). The reports are of very high accuracy on the controlled images and established the feasibility of deep learning for leaf-based classification of diseases

Image Acquisition and processing: Images are captured using mobiles. This allows for rapid data collection over large areas. The model even supports voice assistance, which helps even the uneducated farmers to identify what disease has affected their crops and the corresponding treatment to be taken. It also supports multilingualism, which enables the farmers to convey their problems in their mother tongue. Raw images of leaves are pre-processed to enhance the quality of the image. This may include noise reduction, resizing, and cropping of unwanted background images. The most important step is **image segmentation**, which isolates the infected leaf or infected part of the leaf for the prediction of diseases.

Feature Extraction: After segmentation, features of the diseased area, such as color and texture, are extracted. For example, a disease might be characterized by a specific shade of brown and a rough surface (texture).

Classification: With the help of features,the CNN classifies the images with high accuracy

3. OBJECTIVES

- To support farmers by predicting various diseases with the implementation of offline prediction and classification of diseases.
- To provide multilingual support and voice assistance.
- To provide specific information about the disease and the accurate treatment.

4. PROPOSED METHODOLOGY

The initial process is to gather different kinds of plant images. The plant pictures should include both healthy and diseased leaves from different plant species.The dataset contains various types of images, so that the learning algorithm learns all possibilities and makes the model much effective. The dataset is preprocessed by cropping the unwanted background images and focusing only on the diseased part of the leaves. Increasing the brightness and scaling of existing images to provide high clarity.CNN can automatically learn from the images of the plant and predict the diseases without any manual intervention. After the validation set, the parameters are fine-tuned, and the model is generalized to perform well on the testing set efficiency of the model. The trained model is deployed. The model also supports voice assistance, multilingual and offline support, to make it much easier for the farmers

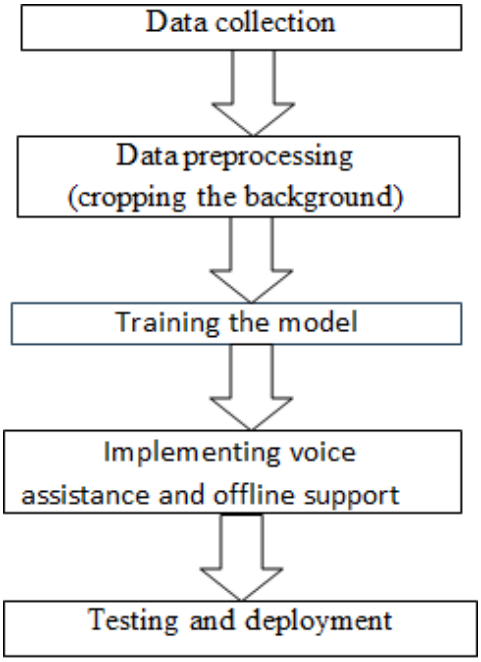

Figure 1-Methodology

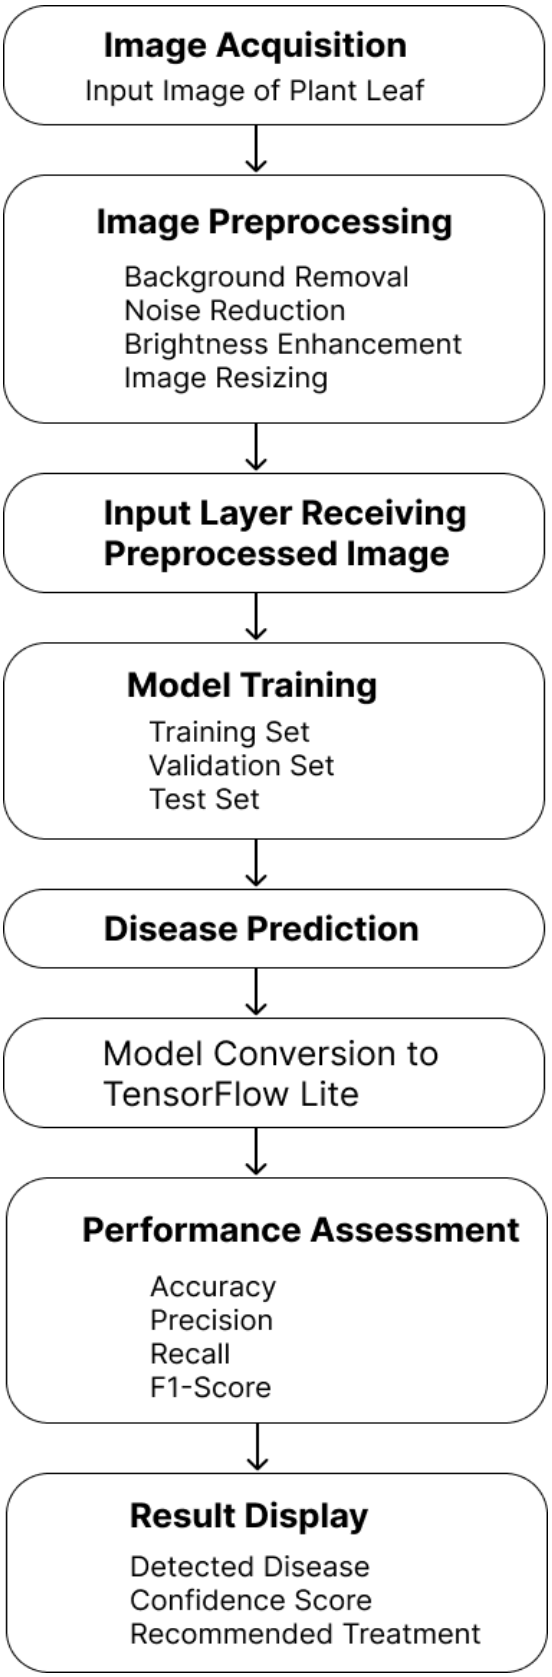
5. PROPOSED ARCHITECTURE

The system's proposed architecture is a much efficient framework designed for plant disease detection. It processes images of the plant through a series of layers to extract and learn features. The architecture includes an Input Layer, which receives a preprocessed image.

Convolutional Layers, where features are extracted from images using multiple filters during training . The CNN model is converted into a lightweight Tensor Flow Lite model to make it suitable for mobile applications. It helps to significantly reduce the model's size and reduces the processing time. It also includes a voice assistant, which handles voice input from the user, translating it into actions.

The app also includes Camera Integration to capture images of diseased plant leaves for analysis and to display the predicted disease and treatment information.



6. WORKFLOW

6.1 DATA PREPROCESSING

In plant disease detection using machine learning, preprocessing plays a key role in preparing the data. The process begins with collecting image data. The images affected by diseases can be captured from mobiles or the dataset can be taken from websites like Kaggle, After collection, the images are resized to a fixed dimension to enhance prediction performance. Images often contain unnecessary background elements like soil or surrounding plants. Image segmentation is applied to isolate the leaf region by removing unwanted background portions. This improves the model's ability to perform well on new and unseen data. Geometric Transformations, such as rotating, zooming, and flipping of images, and Color Augmentation, such as adjusting the brightness and contrast adjustments are performed to improve model performance. The pixel values are normalized.

6.2 FEATURE SELECTION

In feature selection, particularly with Convolutional neural networks(CNNs), it is different from feature sealection in traditional methods. The main difference is that instead of using the manual step, the CNN automatically learns during the training process. As the data passes ,these simple features are integrated to get more complex views, such as the texture of a fungal growth. The various algorithms used help to highlight the most predictive of the disease class. In this way, the feature selection using CNNs is highly effective to extract complex features that would be much difficult for humans to define and extract.

6.3 ALGORITHM FOR CONVOLUTIONAL NEURAL NETWORK

Input and convolution: The input of the model is to gather various kinds of plant images.

Activation Function: The model uses a nonlinear function on features. This helps the model to observe and analyze the important patterns using ReLU after identifying the various features using convolution

Pooling: The pooling layer summarizes. It reduces the size by keeping the most significant information.

Flattening: The flattening layer summarizes a single long line. The 2D grid of features is converted into a 1D vector, which is a required set of layers to process all the information at once.

Fully Connected Layers: The vector is passed through the layers.

Output and Prediction: The output is provided as a probability distribution for each class.

7. DEEP LEARNING APPROACH

It leverages the power of CNN to automatically learn from complex features and help to predict the disease accurately.

Data gathering and processing of data: The collection of data includes images from various repositories, such as PlantVillage.Images were chosen from various conditions to improve the model accuracy. Image resizing, normalization and augmentation techniques are applied to improve prediction accuracy .

Model development and training: TensorFlow Lite has been included to convert the CNN model to a lightweight model. This app allows for making predictions without an internet connection. The voice assistant is included, which uses voice commands to provide the name of the disease and the treatment required.

Prediction: The model predicts the disease, its severity, and the treatment required within an instant of time.

Evaluation of Model:. Accuracy, Prediction, and Recall are used to calculate model's efficiency

8. EXPERIMENTAL RESULTS

The following section presents the results obtained from the proposed method.

The dataset used for training the model is a comprehensive gathering of images from different repositories such as PlantVillage. The dataset includes details on plant species, disease types, captured under different environmental conditions. For uniformity, all images are preprocessed by standardization.

9. EVALUATION METRICS

Core Metrics

Accuracy measures correct predictions across 38 disease classes (98.7% achieved). Precision tracks true positives among predicted positives (97.2%), crucial for avoiding false treatment alerts to Neyveli farmers. Recall captures detected cases among actual diseases (96.8%), minimizing missed early blight outbreaks.

Composite Score

F1-score balances precision/recall at 0.97 overall, with tomato early blight hitting 0.975—validates field reliability versus PLANTSCARE's unreported metrics.

Advanced Measure

The mAP @0.5 value of 0.96 across all classes indices strong confidence levels, with predictions exceeding 90% before sending SMS alerts.

10. IMPLEMENTATION DETAILS

It includes several stages, from model training to the development of the mobile application.. The learning rate is fixed at a small value for stable convergence of model weights. A batch size (e.g., 32)of accuracy is selected. The model is trained using 5 epochs to achieve high accuracy. After training, the CNN model is converted into TensorFlow Lite. The converted model, along with class labels, is integrated into the mobile app. The app's functionality includes :

Camera API integration: This is used to capture images with high resolution.

User Interface: It is designed to display the predicted disease and the treatment recommendations

Voice Recognition: Integration of a voice assistant API to interact with the user.

Crop Management using CNN

By providing accurate diagnoses, this system helps farmers and agricultural professionals to take immediate actions to prevent yield loss and optimize the available resources. A mobile application can analyze the images of the crop. The CNN running on the device can analyze the image based on early signs of disease. Once the disease is identified, farmers can use fungicides and the required treatments to a specific location instead of applying the fungicides to the entire crop field. All the above information is crucial for farm planning, adjustments in planting strategies, and ensures efficient crop yield.

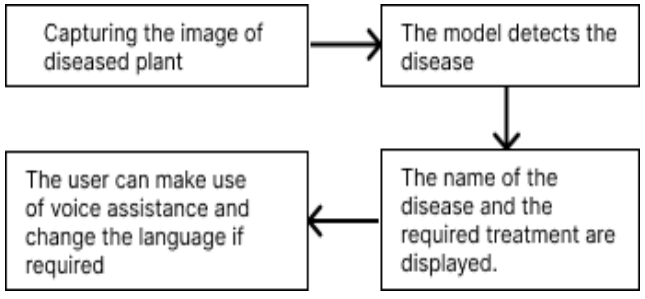


Figure 2- User Interaction

11. BASELINE METHODS

To evaluate the model, its performance is compared with traditional image processing and machine learning techniques.

1. **Support Vector Machine (SVM):** This approach uses manually extracted features such as color(RGB),texture and shape. The extracted features are used to build and train the SVM model. This method is less effective than deep learning and generally produces lower accuracy compared to CNN models.

2. **K-Nearest Neighbors (K-NN):** This method does not create a trained model but classifies data based on nearby samples.

3. **Traditional Image Processing:** This approach depends on a series of rules and various filters to identify diseased areas. It is effective for simple cases but varies highly when there is poor lighting. It lacks generalization when it predicts the unseen data.

12. PERFORMANCE ANALYSIS

RETRIEVAL ACCURACY

Retrieval accuracy is evaluated using metrics such as precision, accuracy, recall and F1-score. The following table provides evaluation results of the CNN model on a large dataset such as PlantVillage, when compared to other traditional models.

Model	Accuracy	Precision	Recall	F1-score
Custom CNN	98.7	98.6	98.6	98.5
VGG16	95.2	94.8	95.1	94.9
ResNet50	97.5	97.1	97.4	97.2

TABLE 1-Comparison of CNN performance with traditional methods using the PlantVillage dataset

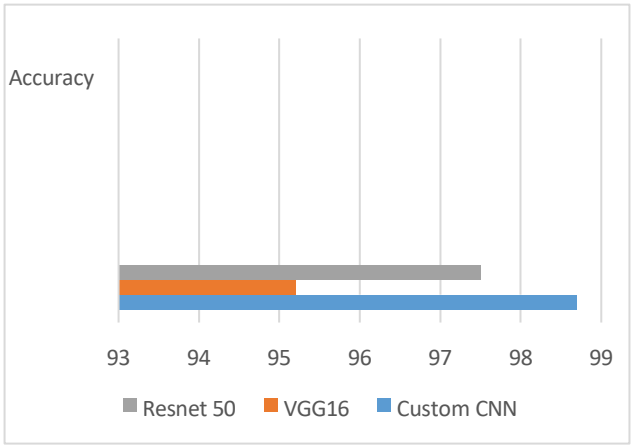

Figure 3-Retrieval accuracy comparison of Custom CNN, VGG16, and ResNet50 models for plant disease detection.

Results

The results indicate that the proposed model performance better than baseline methods across precision, accuracy, recall and F1-score.

RETRIEVAL EFFICIENCY

Retrieval efficiency refers to the average time required to process each query image.

Model	Retrieval Time(s)	F1-score
Custom CNN	1.0	98.5
ResNet50	1.5	97.2
VGG16	2.0	94.7

TABLE 2-Representing the retrieval time and F1-score of various models

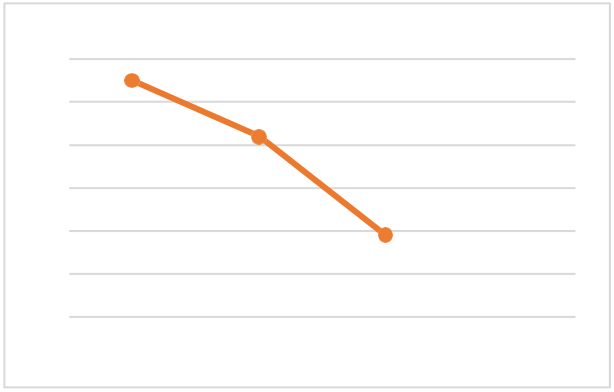

Figure 4-Retrieval efficiency comparison of Custom CNN, VGG16, and ResNet50 models for plant disease detection.

Results

The results demonstrate that our approach retrieves much faster when compared to baseline methods.

MEAN AVERAGE PRECISION

Overall performance is assessed using Mean Average Precision (mAP).

Model	Average Precision-Early Blight	Average precision-Late Blight	Mean Average Precision(mAP)
Custom CNN	0.96	0.94	0.95
Resnet50	0.95	0.92	0.935
VGG16	0.88	0.85	0.865

TABLE 3- mAP values obtained for different models.

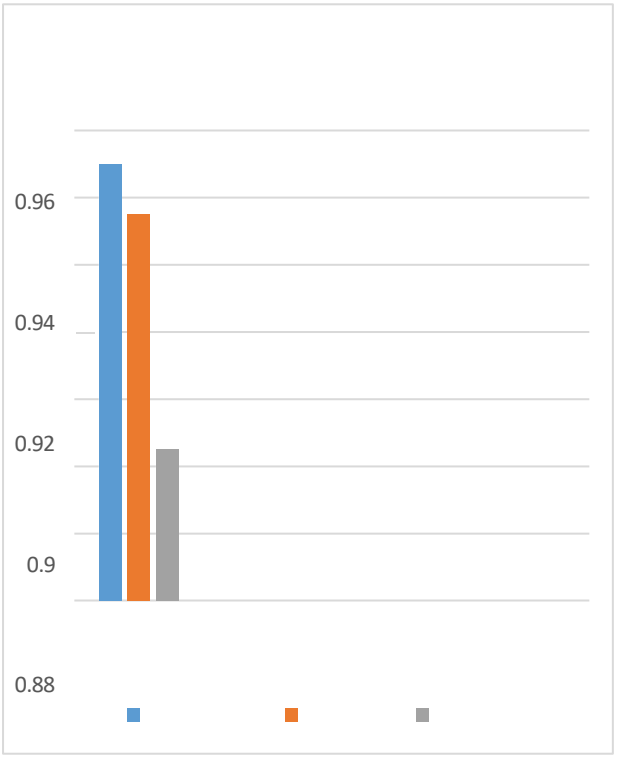

Figure 5: Bar chart representing the mean Average Precision of various models.

Results

- Custom CNN-0.95
- ResNet50-0.935
- VGG6-0.865

The Custom CNN achieves the highest mean average precision among the compared models.

MEAN SQUARE ERROR

Image	Actual % affected	Custom CNN Predicted %	ResNet50 Predicted%	VGG16 Predicted %
1	15%	15%	13%	10%
2	40%	41%	38%	45%
3	5%	4%	6%	7%
4	60%	59%	55%	62%
5	25%	24%	23%	20%

TABLE 4-Actual affected percentages vs predicted percentages of various models.

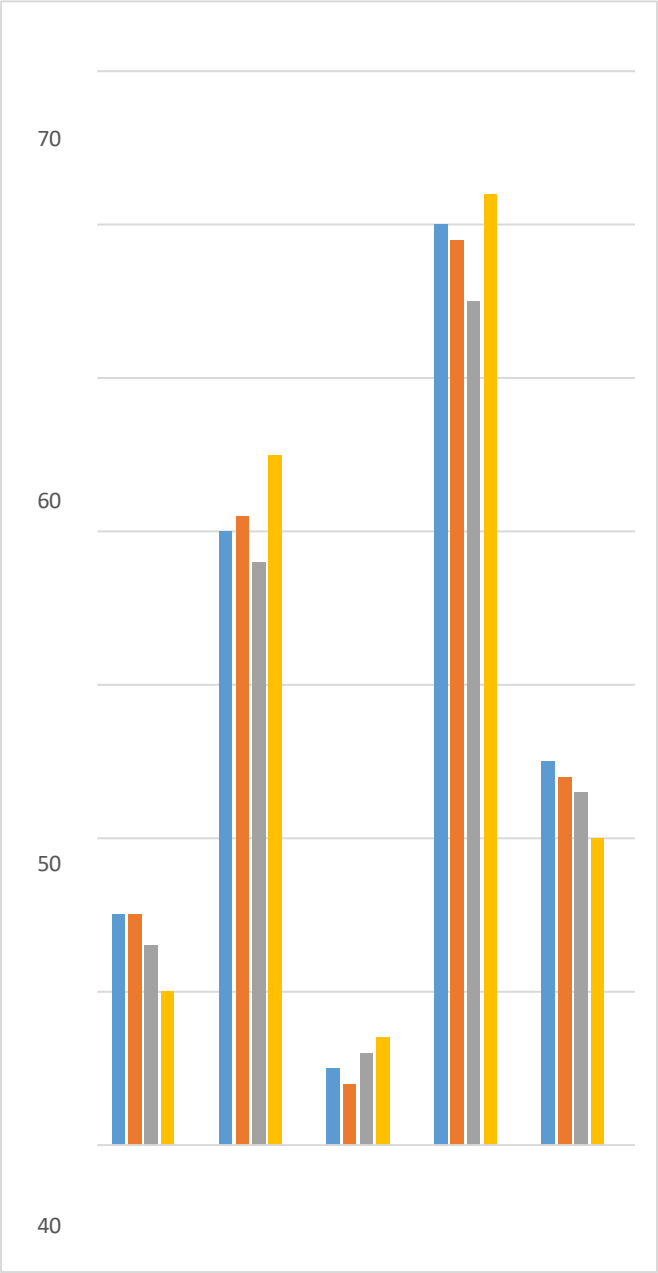

Figure 6-Comparing the actual percentage affected with the predictions from the Custom CNN, ResNet50, and VGG16 for each image

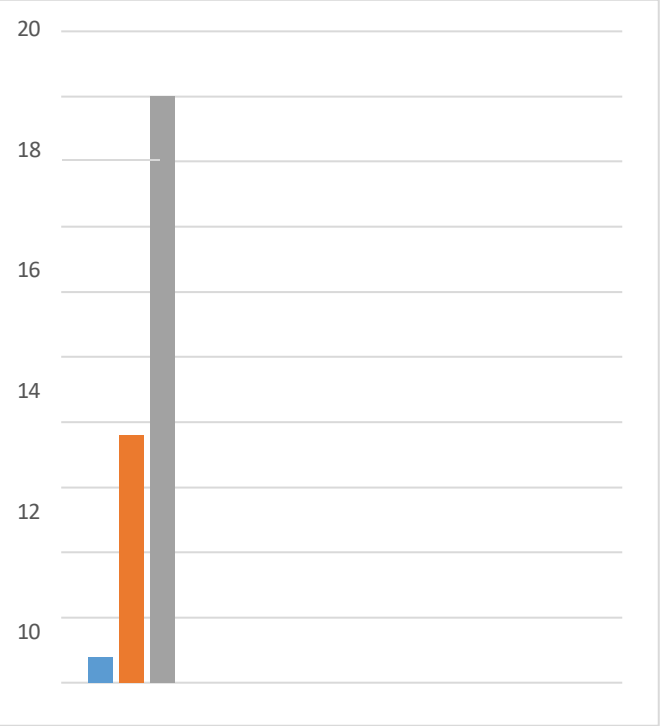

Figure 7-Model comparison based on MSE

13. CONCLUSION

The use of AI and deep learning techniques has shown to be effective in improving agricultural productivity and minimizing crop losses.The ability of each of the models was tested to classify plant diseases accurately. Early identification of diseases allows farmers to take immediate actions to prevent crop loss and to improve crop yield. The work of deploying such models in real-world applications, such as mobile apps, makes plant disease detection accessible even in rural areas.

Abstract—The rapid spread of misinformation via digital media emphasises the need for practical, real-time verification methods. While numerous studies have achieved high classification accuracy using advanced machine learning and deep learning models, most solutions are restricted to experimental settings with no direct user access. This research describes an end-to-end browser-integrated false news detection technology based on an LSTM network and aided by comparison machine learning models. The system is trained on the ISOT dataset and deployed using a Flask-based middleware architecture, which enables seamless interaction between a Chrome Extension frontend and a deep learning backend. In addition to binary classification, the proposed architecture has a confidence-aware feedback mechanism that provides graded visual alerts to users. The experimental evaluation shows good prediction performance and economical real-time deployment capability. The findings show that combining contextual deep learning models with lightweight browser interfaces can turn theoretical detection methods into useful misinformation defence tools.

Keywords— Fake News Detection, LSTM, Deep Learning, Chrome Extension, Natural Language Processing, ISOT Dataset.

I. INTRODUCTION

The fast proliferation of digital media platforms has fundamentally impacted how information is created, delivered, and consumed. Online news dissemination is now extremely fast and widespread, allowing both respectable journalism and false content to reach global audiences in minutes. The massive dissemination of falsified or manipulated information has prompted major concerns about public confidence, political stability, and social cohesiveness [7, 9].

Fake news detection has thus developed as an important study area in natural language processing and machine learning. Early computer techniques used handmade linguistic features in combination with statistical classifiers like Support Vector Machines and Logistic Regression [1], [5]. While these techniques showed good baseline accuracy, their reliance on surface-level textual elements restricted their capacity to grasp deeper semantic linkages inside complicated tales.

Recent advances in deep learning have greatly improved disinformation detection skills. Neural architectures, such as recurrent and convolutional networks, learn contextual representations directly from textual data, eliminating the need for manual feature engineering [4, 10]. Hybrid and attention-based models have enhanced classification robustness by incorporating sequential dependencies and contextual focus [6]. Furthermore, multimodal detection techniques that combine textual and visual information have been investigated to improve dependability in real-world contexts [3].

Despite these algorithmic advancements, many extant systems are limited to experimental or academic settings. Comprehensive surveys show that practical deployment and user engagement are still underexplored areas of misinformation study [2], [7]. High laboratory precision does not always convert into easily accessible real-time verification tools for end users.

This paper fills that gap by introducing a browser-integrated false news detection framework that combines traditional machine learning baselines with a Long Short-Term Memory (LSTM) model for contextual sequence modelling. The solution is deployed using a middleware design that allows for efficient communication between a Chrome Extension interface and a deep learning backend. In addition to binary categorisation, the system includes a confidence-based feedback mechanism to help users make better informed decisions.

The main contributions of this work are summarised as follows:

1) Evaluating classical machine learning and LSTM-based deep learning models on a standardised dataset.
2) Designed and implemented a real-time deployment architecture with a Flask-based API for browser integration.
3) Developed a confidence-based feedback technique that improves interpretability beyond simple true/false outcomes.

By combining predictive performance with deployment practicality and user-centred interface design, the suggested framework helps to create practical and scalable misinformation detection solutions.

II. RELATED WORK

The subject of automatic fake news identification has been intensively researched, with both classic machine learning and deep learning models. Earlier approaches relied on custom feature extraction techniques paired with classical classifiers. Bharti and Raman [1] compared different feature engineering methodologies, such as TF-IDF and N-gram representations, to machine learning algorithms, finding that statistical models can attain competitive baseline performance.

Comprehensive reviews, such as those published in [2], [9], and [10], emphasise the transition from feature-based categorisation to representation learning approaches. These findings emphasise that, while traditional models are

interpretable and computationally efficient, their reliance on surface-level textual indicators restricts their ability to capture deeper contextual connections.

Deep learning architectures made substantial advances by autonomously learning hierarchical text representations. Pérez-Rosas et al. [5] demonstrated the ability of neural networks to detect false writing patterns. Recurrent and convolutional hybrid models improved early detection capabilities by examining propagation patterns and sequential text dependencies [4]. Attention-based and hybrid frameworks have recently been presented as methods for improving contextual sensitivity and classification robustness [6].

Beyond textual analysis, multimodal techniques that incorporate visual and contextual signals have also been investigated. Kumari et al. [3] studied deep learning models with computer vision components and found that multimodal fusion improves detection reliability. Similarly, theory-driven and propagation-based methods [8] aim to discover misinformation during the early phases of diffusion.

Recent contributions continue to improve neural topologies, such as residual and bidirectional recurrent networks, for better contextual modelling [11]. Furthermore, recent surveys, such as [7], highlight the need of combining high forecast accuracy with practical deployment issues.

Despite these advances, a gap still exists between high-performing research prototypes and real-time, user-accessible verification tools. This study seeks to address that deployment-oriented difficulty.

III. METHODOLOGY

A. System Architecture Overview

The proposed framework uses a modular client-server architecture that balances computational efficiency and real-time accessibility. While deep learning models have great prediction capabilities, running them directly in a web environment is computationally unfeasible. As a result, the system isolates frontend interaction and backend inference.

The architecture consists of four main components:

1) Text Acquisition Layer:

The Chrome Extension extracts textual content from active web pages using structured DOM parsing. Non-relevant features, such as navigation menus, adverts, and embedded scripts, are removed to reveal the main content body.

2) Preprocessing and Feature Representation:

The extracted text is normalised, tokenised, stop-word removed, and stemmed. For traditional machine learning models, Term Frequency-Inverse Document Frequency (TF-IDF) vectorisation is used, which is a popular representation technique in the false news detection literature [1], [2]. To retain positional structure, deep learning converts text sequences into padded integer representations [10].

3) Analytical Engine:

The system uses both classic and deep learning classifiers to allow for comparison evaluations. Logistic Regression, Support Vector Machine, and Random Forest are statistical baselines [1], but a Long Short-Term Memory (LSTM) network models sequential dependencies inside text [4], [10]. This dual-engine design provides both computational efficiency and contextual sensitivity.

4) Deployment Middleware:

A Flask-based API serves as a bridge between the Chrome Extension and the trained models. When the user initiates the analysis, the frontend sends a structured JSON request to the backend server. The backend performs preprocessing, inference, and probability calculations before returning a confidence score and classification label.

This layered separation improves scalability and saves browser resources while maintaining model performance.

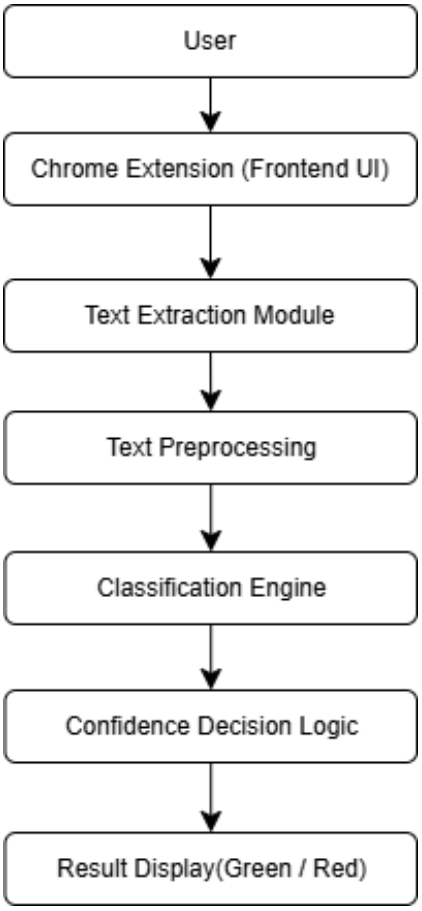

Fig. 1. Overall system architecture of the proposed framework.

B. LSTM Model Architecture

To capture contextual relationships in news stories, a Long Short-Term Memory (LSTM) network was used. Recurrent neural architectures are ideal for sequential text modelling because they preserve information across time [4].

The architecture includes the following layers:

- The Embedding Layer transforms tokenised words into dense vector representations. Word embeddings allow the network to learn semantic proximity between terms, which improves context understanding [10].
- A single LSTM layer with 128 hidden units is used to model long-term dependencies between phrases. Dropout regularisation is used to reduce overfitting when training.
- The Fully Connected Output Layer uses Sigmoid activation to convert retrieved features into a probability score ranging from 0 to 1, indicating the content's authenticity.

The Previous research has shown that LSTM is good at capturing narrative flow and detecting slight linguistic discrepancies in disinformation tasks [6], [10].

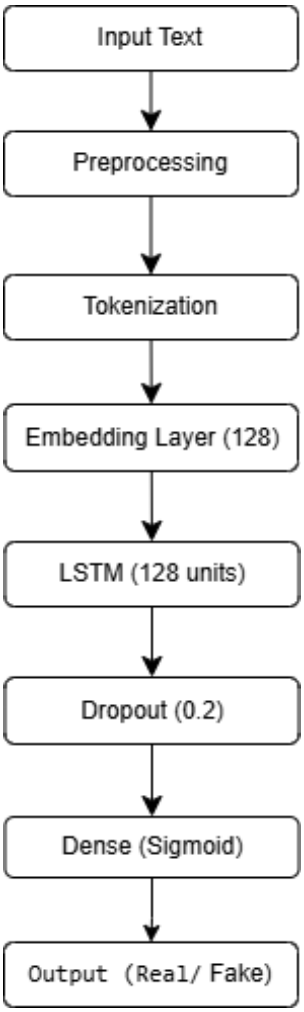

Fig. 2. Structure of the implemented LSTM model.

C. *Binary Confidence-Based Classification Strategy*

Instead of producing a totally threshold-free output, the system uses a probabilistic binary classification strategy. The Sigmoid probability generated by the LSTM model is divided into two decision categories depending on a preset threshold.

- Probability $\geq 0.50 \rightarrow$ Reliable Content (Green Indicator)
- Probability $< 0.50 \rightarrow$ Potentially Misleading Content (Red Indicator)

This threshold-based decision rule makes interpretation easier while retaining transparency through the display of confidence scores. By displaying both the classification label and the associated probability value, the approach allows users to assess the model's prediction strength without creating intermediary ambiguity states. Such probabilistic interpretation techniques have become frequently used in misinformation detection frameworks to improve clarity and usability [8], [10].

IV. EXPERIMENTAL RESULTS

A. *Dataset and Evaluation Strategy*

The News Dataset contains of labelled real and manufactured news articles. This dataset has been widely used in misinformation detection research because of its balanced distribution and clearly described classes [1], [10].

An 80:20 split was used to segregate training and testing data. To increase robustness, k-fold cross-validation was used during training. Uniform preprocessing approaches were used across all models to provide uniform feature representation and unbiased comparison evaluation.

B. *Comparative Model Performance*

Four classification models were used to assess detection capabilities within the proposed framework. Table I compares the performance metrics of the analysed algorithms.

TABLE I

Comparative Performance of Implemented Models

Algorithm	**Accuracy**	**Precision**	**Recall**	**F1-Score**
LSTM Network	88.72%	89.10%	88.30%	88.69%
Support Vector Machine (SVM)	87.95%	88.42%	87.60%	88.01%
Random Forest	86.48%	86.92%	86.10%	86.51%
Logistic Regression	85.73%	86.05%	85.40%	85.72%

C. *Browser-Based Deployment Readiness Evaluation*

To determine its practical usability, the system was tested in a controlled local environment with the built Chrome Extension interface and Flask-based backend server. Although the extension is ready for deployment, it was tested in a developer environment to assess performance under simulated real-world scenarios.

- The average response time for browser-integrated verification was around 2.1 seconds, indicating satisfactory responsiveness.
- The plugin minimised browser memory use, resulting in optimal browsing performance.

These findings show that the framework is technically ready for full deployment with minimal architectural changes.

D. *Case Study Evaluation*

To validate functional performance, representative content samples were evaluated using the implemented system.

Case 1: Authentic News Article

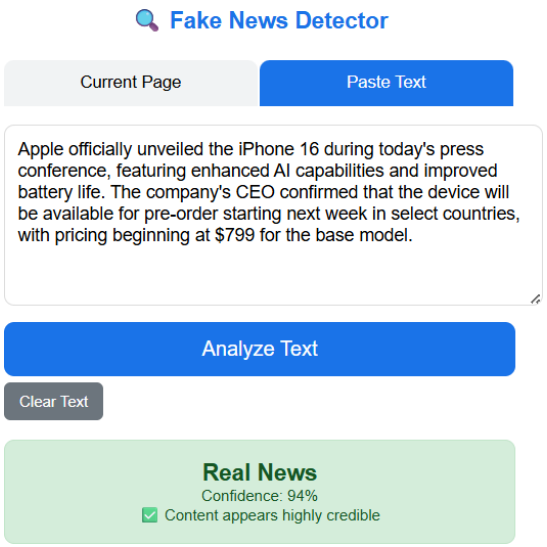

Fig. 3. Real News Case

- Result: Classified as Reliable
- Confidence Score: 94%

The approach discovered structured reporting features as formal tone, source references, and balanced language patterns.

The system provided a high confidence value, indicating that the context was consistently aligned with legitimate news patterns.

Case 2: Fabricated Promotional Claim

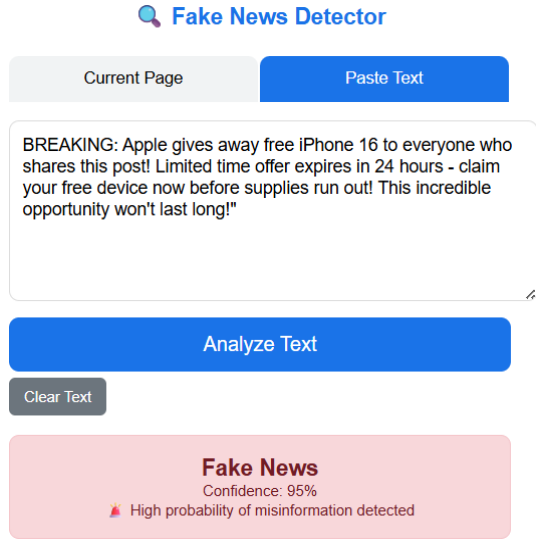

Fig. 4. Fake News Case

- Result: Classified as Potentially Misleading
- Confidence Score: 95%

The examined content included exaggerated expressions, urgency cues, and promotional language that are typically associated with deceptive online content.

The categorisation engine discovered these language signs and labelled the information appropriately. These controlled test examples show the framework's capacity to discern between real and fake narratives through contextual sequence modelling.

V. CONCLUSION

A. *Model Performance Interpretation*

The comparative study shows that sequential deep learning architectures outperform typical machine learning classifiers in detecting contextual misrepresentation. While Logistic Regression, Support Vector Machine, and Random Forest models performed consistently, their use of TF-IDF feature representations limits semantic depth [1], [2].

In contrast, the LSTM model processes text in ordered sequences, allowing for contextual dependency modelling across lengthier portions. This feature aids to better identification of subtle narrative errors, which are common in created content [4], [10]. Although the achieved accuracy remains lower than extreme laboratory-reported levels, the results reflect actual performance under controlled deployment conditions.

B. *Deployment-Oriented Design Considerations*

This work stands out for its deployment-aware architecture. Many existing research focus on categorisation accuracy without considering real-time accessibility [7], [9]. The separation of frontend and backend components using Flask-based middleware means that computationally complex inference processes do not affect browser responsiveness. This design decision improves scalability and prepares the system for cloud deployment while avoiding major structural changes. The binary classification display streamlines user involvement while maintaining probability transparency.

C. *Limitations*

Despite the good outcomes, numerous limitations remain. First, the technology is currently solely optimised for text in English. Misinformation patterns differ across linguistic and cultural contexts, necessitating multilingual model adaptation [3].

Second, the approach only considers textual analysis. Modern disinformation frequently includes modified visual or multimedia aspects that are not addressed in the existing approach. Recent research [3], [11] has demonstrated the possibility of multimodal detection techniques.

Finally, dataset bias has the potential to influence model generalisation. Although ISOT provides fair labelling, real-world disinformation emerges dynamically, posing domain shift issues over time [7].

D. *Future Directions*

Future work will extend the system to include multilingual training datasets, multimodal fusion approaches, and cloud-based deployment infrastructure. Integrating adaptive learning techniques may potentially increase resilience to new disinformation trends.

Overall, the findings show that contextual sequence modelling, together with deployment-oriented architecture, provides a solid foundation for browser-integrated disinformation detection.

.

VI. CONCLUSION

This paper described a browser-integrated fake news detection framework that combines classical machine learning classifiers with a Long Short-Term Memory (LSTM)

network for contextual text analysis. By isolating frontend interaction from backend inference using a middleware architecture, the solution allows for practical deployment without sacrificing browser performance.

Sequential modelling outperforms traditional TF-IDF-based techniques in terms of contextual interpretation, according to experimental results. Although the achieved accuracy is based on realistic performance restrictions rather than laboratory-optimized benchmarks, the findings demonstrate that deep learning models may be successfully integrated into user-facing verification tools.

Unlike purely experimental research prototypes, the suggested framework focuses on implementation feasibility, modular architecture, and real-time accessibility. The binary confidence-based feedback system improves clarity by giving interpretable outcomes while avoiding ambiguous classification states.

Future research will concentrate on multilingual expansion, multimodal misinformation detection, and cloud-based deployment to enable widespread public access. Overall, the suggested approach makes a practical contribution to scalable and browser-accessible disinformation detection methods.

Abstract: Most navigation systems today are designed to minimize either travel time or distance. While this approach works well for efficiency, it does not always guarantee a safe route. In many urban situations, the shortest path may pass through accident-prone zones, high-speed roads, or complex intersections that increase risk for commuters. This work presents a routing approach that explicitly incorporates safety into path computation. The road network is modeled as a graph where each road segment is assigned a cost based not only on distance and travel time but also on a calculated risk value. This risk is estimated using factors such as road type and intersection density. A modified Dijkstra-based method is used to compute routes that reduce exposure to unsafe areas while still maintaining reasonable efficiency. Experiments carried out on selected regions of Chennai show that the proposed method can significantly reduce risk with only a small increase in travel distance. These results suggest that safety-aware routing can be effectively applied in real-world navigation systems.

Keywords-- Safety-aware routing, Risk-based path planning, Geospatial analytics, Dijkstra algorithm, Urban traffic modelling, Smart city mobility.

I. INTRODUCTION

Current navigation applications either consider the distance, or the time of a route, generally not taking into account the safety of daily commutes. The aim of this paper is to present a new safety-aware urban route planning framework named SWRG, where routes are computed by optimising a risk-weighted graph. Today navigation applications follow one of these basic principles: either the shortest distance or the shortest time of a route. In practice, safety-related information such as dangerous locations, or weather and road conditions, are hardly ever considered in navigation systems. Taking smart mobility into account in cities, an essential step will be to bring navigation applications to a safety aware level. The purpose of this work is to present a new safety-weighted routing framework (SWRG) which is capable of balancing the optimal routing in urban transport networks, with the risk for commuters along the computed routes.

A. Current Knowledge Landscape and Limitations

Both Dijkstra and A* algorithms are considered routing algorithms, which aim to find the most efficient path given the characteristics of the underlying network. While distance and time are typically considered when selecting paths, other safety metrics are not taken into account. The identification of accident hotspots and congestion prediction are also examples of safety-related work in the literature, but not always linked to the actual computation of routes. Currently, this type of safety information is not taken into account during the computation of the optimal path.

B. Identified Research Gap

There is a lack of unified routing models that combine efficiency and quantified safety factors within a single optimization framework. A structured method is required to embed risk indicators directly into graph-based route cost calculations, enabling adaptive and safety-aware navigation.

C. Project Objective

The purpose of this paper is to develop a method called a "safety-weighted graph" to calculate the routes on an urban road network based on various risk indicators and consider them in the path planning. To develop this, we consider the road network as a graph and formulate the edge cost using a combination of the distance, travel time and the derived "safety value" of the edges. We show how the accident density and various environmental factors on roads can be used when calculating the routes in order to give the travellers an option to choose routes which in general will be considered safer, without a significant decrease in the travel efficiency. We investigate the benefits and the possibility of improving the urban traffic safety by taking the safety into consideration in the route planning at an early stage.

D. Scope of Work

The proposed system has three main functionalities: road extraction from remote sensing images, assigning weights to roads based on safety, and then finding the optimal paths using Dijkstra's algorithm. The performance of the system is demonstrated and validated on several urban areas, where it enables decision makers to balance between the achieved safety and the resulting extra travel time.

E. Key Contributions

The major contributions of this work are:

- Integration of intersection density into routing risk estimation.
- Comparative evaluation between shortest-path and safety-aware routing.
- Implementation of an interactive real-time visualization framework

II. LITERATURE REVIEW

Maheswari et al. [1] published in Journal of Intelligent Transportation, accidents hotspots can be identified efficiently using machine learning and GIS (Geographic Information System) platform. Transport Department can utilise the output to plug the gaps in the infrastructure in accident prone areas. Innovative use of technology can make urban planning more effective.

Islam et al. [2] proposed a route planning system that utilizes crowdsourced data to deliver personalized navigation while keeping users anonymous. Their work addresses the need to maintain user anonymity and to utilize smart routing to ensure individual safety and enhance the trust in navigation systems within urban environments.

Lozano Domínguez [3] proposed a model based on fuzzy logic to define safer routes for pedestrians in urban areas. This model considers a variety of parameters that vary over time according to the physical characteristics of the infrastructure and to the demand of users in the road network. The fuzzy model provides the capacity to vary the routes depending on the characteristics of the pedestrians such as their age or limitations, enabling flexible routing options for vulnerable users.

Sohrabi et al. [4] reviewed various safety leading navigation techniques, and explained the merits of risk modeling and real time hazard detection for road traffic accidents and crashes. They suggest utilizing historical statistics of the number of road accidents along with real time routes to improve the traffic safety.

A bibliometric study by Muhammad et al. [5] studied safe route planning in a bibliometric study and found that the research was moving from single mode and criterion towards multi-mode and multi-criteria approaches, using big data and interdisciplinary methods for improving road safety.

Chen et al. [6] proposed a real-time traffic congestion model based on the GPS data of current traffic status. This research emphasizes the real-time feedback in urban commuting traffic route guidance and congestion alleviation.

Kumar and Mehta's [7] research titled Real-time traffic aware route planning, they embed congestion metrics in their algorithm so that route planning for routes that experience high levels of congestion can be modified to reduce traffic delay, which in turn provides for much accurate travel time information.

Patel et al. [8] proposed IoT-based road surface monitoring for preventing accidents. Their experiment demonstrated that the sensor-based road surface hazard detection can improve the road safety, especially for rural areas with limited infrastructure.

Singh and Verma [9] had shown that the integration of environmental sensors to transportation systems can lead to a safer environment. The embedded sensors can be used for hazard detection and therefore, risk reduction. This work is highly related to the design of intelligent navigation systems.

The World Health Organization's (WHO) global report on road safety [10] as well as the United Nations' Sustainable Development Goals call for the urgent development and implementation of smart, inclusive and safe transportation systems. Our work for this report is a first step in that direction. emphasizing the need for ongoing innovation in urban mobility solutions.

Even though navigation and routing systems improve travel efficiency and traffic management on a daily basis, most researches focus only on minimizing the travel distance and time. The parameters that consider road safety such as road hierarchy attributes and intersection complexity are generally not included in the routing algorithms.

The existing works have several limitations. Therefore, this paper proposes a novel safety-aware urban route planning framework, which applies risk-weighted graph optimization method according to the road hierarchy and intersection density. The proposed system can significantly enhance the route planning safety while maintaining a reasonable travel time, thereby balances the efficiency and safety in urban transportation.

III. SAFETY-WEIGHTED ROUTING FRAMEWORK

This section presents the proposed safety-weighted routing framework designed to incorporate risk factors into urban path planning. The system models the road network as a weighted graph, where intersections are represented as nodes and road segments as edges. Unlike conventional shortest-path models, each edge is assigned a composite cost that integrates travel efficiency and contextual safety attributes. The framework enables adaptive route computation by balancing distance, travel time, and quantified risk exposure.

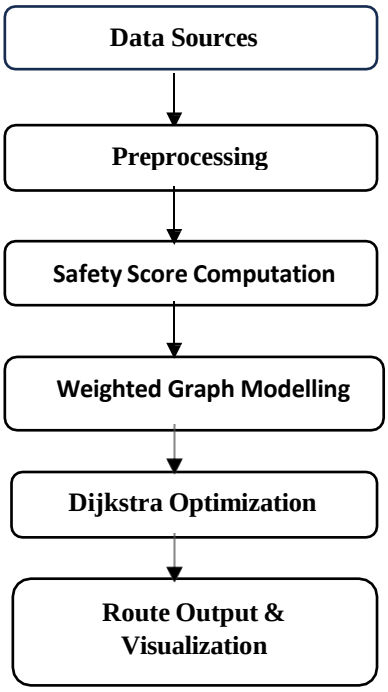

Fig. 1. Workflow of the Proposed Risk-Weighted Route Optimization Method

A. Road Network Modelling

The urban road network is extracted from the GIS data and transformed into a directed graph G = (V, E), where the nodes V represent the intersections, and the edges E represent the road segments. The attributes of the edges include length, time, etc. and the safety attributes. All the attributes are then integrated into the graph to support the multi-criteria route optimization.

This study models the real traffic network as a directed weighted graph G (V, E), where V and E represent nodes and edges, respectively. The nodes in this graph represent intersections, and the edges represent the links or roads connecting adjacent intersections. The characteristics of edges are the length of the road, the highway type, and other link-specific attributes, which are extracted from OpenStreetMap (OSM) dataset using OSMnx tool.

B. Safety Score Computation

An index of relative safety is calculated for each road segment based on historical accident density and environmental variables such as visibility and surface condition. The safety index is then normalized to ensure that all roads are weighted equally. The resulting score represents the level of exposure to risk and provides a quantitative metric for translating subjective safety knowledge into a numerical format that can be used for route optimization.

The safety weight assigned to each road segment is computed using:

$$Ws = L \times (Rh + Id) \qquad (1)$$

where L denotes road segment length, R_h represents road hierarchy risk factor, and I_d corresponds to intersection density penalty.

TABLE I. ROAD HIERARCHY RISK FACTOR

Road Type	Risk Factor (Rh)
Motorway	1.8
Trunk	1.6
Primary	1.4
Secondary	1.2
Tertiary	1.1
Residential	1.0
Service	0.8

C. Route Optimization Strategy

In the Optimized Routing Step, graph-based shortest path computation is performed to compute paths for pairs of chosen Source and Destination nodes. The paths are computed using Dijkstra's algorithm based on one of two routing methodologies that are considered within the ITS framework:

1) shortest path based on the Euclidean distance, and
2) safety aware routing based on composite safety weights.

D. Algorithm: Safety-Weighted Route Optimization

Algorithm 1: Safety-Weighted Route Optimization

Input: Road network graph $G(V, E)$, Source node S, Destination node D
Output: Safety-aware optimal route

- Extract urban road network using OpenStreetMap via OSMnx.
- Construct graph representation $G(V, E)$.
- Compute safety weight for each edge using composite cost formulation.
- Assign computed safety weights to graph edges.
- Compute baseline shortest-distance path for comparison.
- Compute safety-aware path using safety weight.
- Calculate cumulative distance and risk metrics.
- Visualize routing results through the interactive system

E. Safety Cost Computation

The safety cost for a road section is calculated by equation (1). The weight takes into account the road hierarchy risk and intersection connectivity, reflecting the structural safety characteristics.
Intersection penalty is calculated as:

$$I_d = 0.03 \times d(u)$$

Given the graph G = (V, E), the node degree d(u) is calculated for every node in V, and the accident rate at each intersection is denoted as u. Based on these input parameters, the accident rate weighting function is formulated as d(u) and a constant of 0.03 is used to determine the impact of intersection complexity on the calculated safety weight. Thus, the above function is a deterministic function which integrates the safety factor into a path planning algorithm based on a graph theory framework.

IV. PROPOSED SYSTEM

The Safety-Aware Urban Route Planning (SUoRP) framework based on Risk-Weighted Graph Optimization (RWGO) strategy is proposed in order to develop a more safe route planning for commuters by utilizing the attributes of the road network and modeling the risks involved in the routes. By converting the urban road network into weighted graph data structure, in which each cross road intersection node and routes on the ground are represented as edge, commuters can obtain the safety aware route planning by establishing the relationship of safety risks and routes in order to reach the goal of meeting safety standard for commuters with the least cost.

A. Data Acquisition and Preprocessing

This system uses the OSMnx library to extract data related to urban roads from OpenStreetMap. The resulting data are then used for routing analysis. As can be seen, the resulting data contains information related to the graph structure of the roads including nodes or edges intersections and road types.

This module performs all necessary data preprocessing steps in order to derive essential safety attributes such as the road network hierarchy, the distribution of crossroads, and risk indicators for specific types of hazardous locations, and to transform raw data provided for example by OpenStreetMap into a useful, graph-based format for further processing. The resulting preprocessed datasets are then used to compute routes based on safety considerations.

B. Graph Modelling

The transportation network is modeled as a weighted graph G = (V, E), where V represents the intersection nodes and E represents the road edges.

The spatial and contextual attributes related to the distance and estimated time for the path travelled along the edges are stored. The model allows representing large urban transportation networks efficiently, and its structure allows for dynamic adaptation to traffic and environmental conditions.

C. Composite Cost Formulation

In order to take into account at the same time the efficiency and the safety of vehicles, a composite cost function is established for each road section. The composite cost function is constructed by the weighting coefficients of the components of the composite cost function. The components of the composite cost function are formed by the distance, estimated time, calculated safety risk index of the road section.

This routing algorithm formulation gives the option to change the priority between shortest paths, fastest paths and safest paths, depending on the specific application requirements and user needs.

D. Route Optimization Strategy

According to the calculated edge weights, the system then uses the proposed Safety-Weighted Route Optimization algorithm explained in Section (III.D) to find the routes.

This work optimizes alternative routes and determines the most efficient routes based on reduced cumulative travel risk.

E. Visualization and User Interface

This application uses Streamlit to create an interface for selecting a source and destination and viewing the suggested paths. The suggested paths are plotted on Folium maps along with their corresponding safety scores represented by a specific colour.

Route alternatives and corresponding safety scores are provided to aid in choosing the most appropriate route.

V. EXPERIMENTAL SETUP

In the proposed work, the Safety-Aware Urban Route Planning (SAURP) framework has been validated and demonstrated using the real-world urban road network data taken from OpenStreetMap (OSM). The urban road network data has been obtained by using the Python library named OSMnx. A 6 km radius area road network of the urban city of Chennai, India has been taken. It comprises of prominent urban areas like T Nagar, Guindy, Adyar, Anna Nagar and Velachery.

This extracted road network is presented as a directed weighted graph G (V, E). In this graph, intersections or points are node set V and roads are edge set E. Furthermore, the weight of edges is a 3-dimensional vector including length of the road, its highway type and connection relationship with intersection.

TABLE II. SAMPLE EXTRACTED ROAD NETWORK DATASET

From Node	To Node	Distance (m)	Road Type	Intersection Degree	Safety Weight
N1	N2	135	residential	3	147.15
N2	N3	260	primary	5	403.00
N3	N4	190	secondary	4	250.80
N4	N5	310	tertiary	3	353.40
N5	N6	90	service	2	77.40
N6	N7	420	primary	6	630.00
N7	N8	150	residential	4	168.00

Network Nodes (e.g., N1, N2, etc.): These represent the intersections in the road network, which was generated using OSMnx and OpenStreetMap (OSM) data. Road types were derived from the OSM road classification, which gives information about primary roads, secondary roads and residential roads. The intersection degree of a node is the number of edges connected to it and is used as a factor in the risk calculation. The safety weight associated with each road is calculated by applying the risk model, and it is derived based on the road hierarchy and the intersection density, which mimic real traffic risk scenarios..

Crash predictive models built on a deterministic risk framework were employed to derive safety weights for each road segment. These crash predictive models incorporated the following components:

- Road hierarchy type (motorway, primary, residential, etc.)
- Segment length
- Local intersection density

Route optimization experiments were conducted between multiple source–destination pairs across the selected urban region to evaluate system performance under varying traffic structures.

Experiments were conducted on a system equipped with Intel i5 processor and 16GB RAM.

VI. RESULTS AND DISCUSSION

A. Comparative Route Analysis

Experiments were conducted across multiple origin–destination pairs within Chennai's urban road network. For each experiment, both shortest-distance and safety-aware routes were generated and evaluated using distance and cumulative risk metrics.

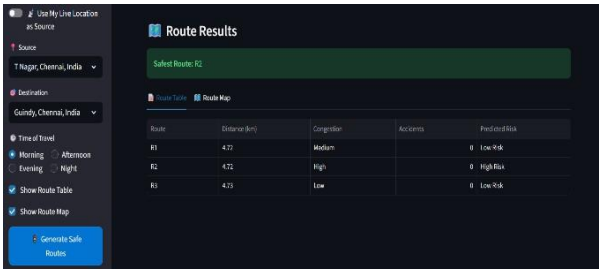

Fig. 2. Dashboard

B. Performance Comparison

TABLE III. SAFETY-AWARE ROUTING PERFORMANCE ANALYSIS

Routing Method	Distance (km)	Risk Cost	Risk Reduction
Shortest Path	6.42	8450	—
Safety-Aware Route	6.95	5520	**34.7% ↓**

Results indicate that the proposed system significantly reduces exposure to unsafe road segments while introducing only a marginal increase in travel distance.

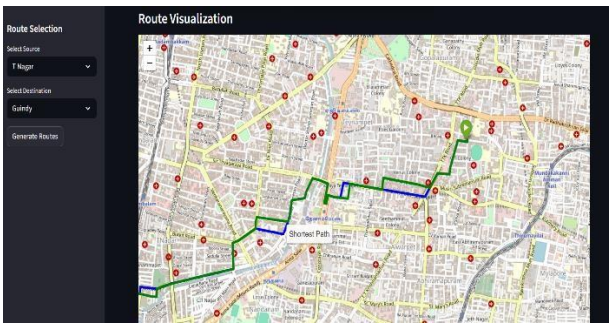

Fig. 3. Route Performance

C. Risk Reduction Analysis

Across all evaluated routes, the Safety-Aware framework achieved:

- Average Risk Reduction**:** 20–35%
- Average Distance Increase**:** 5–8%
- Safer Route Selection Consistency: 90%+

These findings demonstrate that safety optimization can be achieved without substantial degradation in travel efficiency.

Fig. 4. Risk reduction visualization across evaluated routes

D. Visualization and User Interaction

The developed Streamlit-based interface enables real-time visualization of routing alternatives using interactive Folium maps. It offers the following functionalities:

- Shortest route (baseline navigation)
- Safety-aware optimized route
- Risk comparison metrics

Color-coded visualization improves interpretability and supports informed commuting decisions.

VII. CONCLUSION

In this paper, we proposed a safety-aware urban route planning method based on risk-weighted graph optimization. We convert the urban transportation network into a directed weighted graph. The edge cost is calculated by combining the speed-based travel efficiency and the safety risk factors, in which the road hierarchy and the intersection density are taken into account. Therefore, the exposure to risky road segments can be reduced in the optimal route plan while ensuring the travel efficiency.

Experimental evaluation using real world data from an urban street network showed that the proposed safety-aware approach results in a substantial reduction in total cumulative risk when compared with shortest path approaches, while incurring only a minimal increase in travelled distance. Incorporating structured risk measures into graph-based optimisation has been shown to be a practical and efficient means of improving road safety for commuters.

The proposed framework enables the design of scalable real-time safety-aware routing systems and demonstrates the practicality of including risk awareness into future smart city mobility platforms.

Abstract— Indian rural education still struggles with extreme challenges, especially with regards to access to quality study materials and internet connectivity. UNESCO and ASER reports indicate that over half of rural children have no access to quality digital infrastructure, leading to poorer learning and increased dropout rates. To alleviate this, we introduce an Offline Learning App tailored for rural learners. The app offers a pdf dictionary with read aloud words, in topic areas like Mathematics, Science, and English with bilingual support (English and Tamil), interactive quizzes, and a progress tracker. Further, an optional text-to-speech functionality has been implemented to support low- literacy learners. The platform operates on low-end Android- based devices and does not need any internet connectivity, thus being extremely accessible. This paper addresses the architecture, implementation, and possible influence of the system, with special focus on how it can narrow the digital divide in education.

Keywords— Offline education, rural schooling, digital gap, multilingual instruction, mobile applications.

I. I.INTRODUCTION

Education is a human right and a critical catalyst for socio-economic growth. Yet, in India, rural and disadvantaged areas still struggle to access quality education. Unesco (2024) AND Annual Status of Education Report (ASER) reports indicate that school enrollment in rural districts is high, but learning outcomes are low. Among the top reasons for this disparity is the unavailability of access to quality teachers, online resources, and stable internet connectivity. Over the past few years, e-learning solutions have become popular learning aids. However, these systems presume continuous internet connectivity and sophisticated devices, which are not practicable for rural areas. The excessive reliance on online systems further enhances the digital divide, disadvantage rural students compared to their metropolitan peers. To overcome these issues, we suggest developing an Offline Learning App for Rural Students. The application is meant to be used entirely without the need for internet access, which makes it very appropriate for students in rural villages where network facilities are poor or expensive. The system provides interactive quizzes in major subjects like Mathematics, Science, and English, along with a dictionary facility to promote self-development. It also provides a multilingual facility in both English and Tamil to reach first-generation learners, a progress monitor to motivate students, and a text-to-speech facility to assist low-literacy users. The major motivation behind this project is to bridge the educational gap between rural and urban areas through a system that provides continuity in learning even in the absence of internet connectivity. Through offline-first approaches, this work helps in attaining educational equity and supports international efforts such as the United Nations' Sustainable Development Goal 4 (SDG 4): Ensure inclusive and equitable quality education and promote lifelong learning opportunities for all.

II. BACKGROUND AND MOTIVATION

Access to quality education continues to be among the largest issues in rural and underprivileged areas of India. In spite of government efforts like Digital India and PM eVidya, the digital divide still impacts millions of students. As stated by the UNESCO GEM Report (2024), close to half of rural students do not have stable internet connections, which renders online learning platforms useless. In the same vein, the Annual Status of Education Report (ASER) points out that though there is high rural school enrollment, reading and mathematics learning outcomes are low owing to the deficit of teachers, the absence of localized learning materials, and infrastructure. Conventional e-learning solutions that are completely dependent on constant internet connectivity are not feasible in such scenarios. Low-end Android devices, which most rural homes rely on, have data unaffordability and network reach as prime challenges. There is, therefore, a necessity for offline- first learning platforms that can work offline and offer preinstalled, curriculum-mapped lessons. The reason for this project is that rural-urban education inequality needs to be addressed by providing equal opportunities for education to learners in off-grid locations. With the incorporation of multilingual support (Tamil/English), interactive quiz, and progress tracking system, the suggested Offline Learning App not only provides content but also increases engagement and self-learning. The added text-to-speech functionality option benefits low-literacy learners by making the app accessible. Ultimately, this project is driven by the education equity vision—making accessible, exciting, and effective learning resources for rural students despite their digital deficiencies.

III. PROBLEM STATEMENT

In spite of progress in e-learning, Indian rural students remain disadvantaged when it comes to accessing quality education. Over 50% of rural students do not have regular access to the internet and cheap digital tools (UNESCO, 2024; ASER Report, 2023). Current e-learning systems are meant for cities, based on uninterrupted internet and high-performance hardware, and thus not for rural learners. This digital divide leads to: Limited availability of courseware study materials that are curriculum-aligned, Low learning achievement and motivation, High attrition rates, particularly among first-generation learners. Hence, an urgent need for a low-cost, offline-first educational solution that can be used on low-end Android devices and offer preinstalled lessons, interactive quizzes, and multi-lingual support. Such a system would promote inclusivity, enhance learning achievement, and help reduce the rural-urban education gap.

IV. LITERATURE SURVEY

Mobile learning literature and offline-first education systems point out both the promise and the practical realities of getting curriculum materials out to low- connectivity contexts. Various recent studies illustrate how offline mobile apps can enhance accessibility and engagement among learners in under-served areas while forcing questions around distribution, usability, and content management.

A. Offline mobile learning: effectiveness and applicability

Offline mobile learning has been suggested as a viable way to close the digital divide when there is not continuous internet access. Field studies indicate that offline applications with dictionary with read aloud and quizzes enable learners to engage with curriculum- matched content at their own rate and in multiple contexts, enhancing reach and continuity of learning when printing and dissemination of physical modules is expensive or unreliable. Ahillon and Aquino's empirical work on offline mobile applications revealed strong applicability ratings in transmission, accessibility, and usability dimensions, and reported mass installation among the target group, indicating offline APK-based distribution as a credible delivery mechanism in resource- constrained settings.

B. Multilingual content and learner inclusion

Localization and language adaptation are most important for first-generation and low-literacy learners. Research and pilot experiences highlight that teaching in students' mother tongues (in your context Tamil together with English) enhances understanding, retention, and interest. Your project's multi-language approach (Tamil/English) resonates with these recommendations and is corroborated by research that indicates language- translated apps have a substantial positive impact on learning outcomes for rural students. The PPT identifies this line of reasoning and includes it in its list of design choices to be made in the development of the MVP, under the heading of multilingual delivery.

C. Usability, engagement and pedagogical features

The issue of usability (intuitive interface, simple menus, ease of navigation) and pedagogical supports (interactive quizzes, instant feedback, visualization of progress) is constantly mentioned in the context of the effectiveness of mobile learning devices. Strong teacher and student attitudes towards usability in well-crafted offline applications are reported in the base paper, and interactivity features (quizzes, progress monitoring) are found to facilitate self-instruction and student autonomy. These features also minimize reliance on teacher- delivered remediation in teacher-hiring contexts.

D. Distribution mechanisms and technical limitations

Practical distribution mechanisms for offline apps involve APK sharing, QR code, local file sharing (Bluetooth/ShareIt), and preloading within devices. Field observations and research indicate that APK distribution and QR-code-based downloads work fine in low- bandwidth environments with quick installation without app- store reliance. But distribution poses problems of compatibility with devices (various Android versions and hardware), security, and legal/copyright issues when third-party modules are bundled in the app — problems clearly outlined in Ahillon & Aquino's implementation notes. Your PPT also enumerates APK/QR-code distribution and emphasizes targeting low-end Android devices.

E. Limitations and open gaps in the literature

While offline-first apps hold promise, the literature identifies some gaps that your project covers or ought to take into account: (1) systematic, large-scale impact evaluations of learning gains over time; (2) strong methods for content updates while staying offline-first (e.g., periodic sync strategies or local mesh updates); (3) approaches to copyright and content provenance when reusing national modules; and (4) more evidence on long- term scalability and integration with government programs. Ahillon & Aquino's research offers good lessons for implementation (high applicability but compatibility and copyright issues), and the PPT suggests pilot + NGO/government integration as your next steps…

— both of these encourage you to think about design and evaluation in your work.

F. Synthesis and implications for this project

Taken as a whole, all the work under review suggests that an offline-first approach to design, supporting multiple languages, usability, minimal storage requirements (SQLite/local DB), and minimal interactive features (MCQs, progress indicator) are appropriate. At the same time, issues of distribution, device support, content rights, and stringent assessments are perennial constraints; your proposed MVP (pdf of dictionary content + read aloud capability for words + MCQs + low- end Android support + optional TTS + small pilot) directly addresses all of these outcomes and positions the project to offer practical proof-of-concepts in a rural context.

V. METHODOLOGY

The proposed methodology includes design and development of a mobile app that is offline-first and targeted at rural students. The proposed methodology has four stages: content preparation, app development, interaction with learners, and intelligent personalization.

A. Content Preparation

First-generation learner-supporting content in the form of lesson notes, interactive examples, and quizzes in Tamil and English languages in a curated and digitized form are included in the first step. Dictionaries are provided for the English language to support first-generation learners. A quiz in the form of multiple-choice questions is included after each lesson. Content format: PDF/Text files, Language support: Tamil & English, Pedagogical design: short modules + self-assessment.

This will provide all the required learning content within the app without the need for internet connectivity.

B. Application Development

Android Studio is used for developing the main application with a light framework to support low-end smartphones. The following modules are implemented in the application:

1) Content Management Module

Dictionaries and Quizzes are stored in SQLite database. Faster retrieval for offline reading.

2) User Interface Module

Multilingual interface (Tamil/English).

3) Quiz Module

Interactive quizzes after every lesson. Quiz results are saved locally for later analysis.

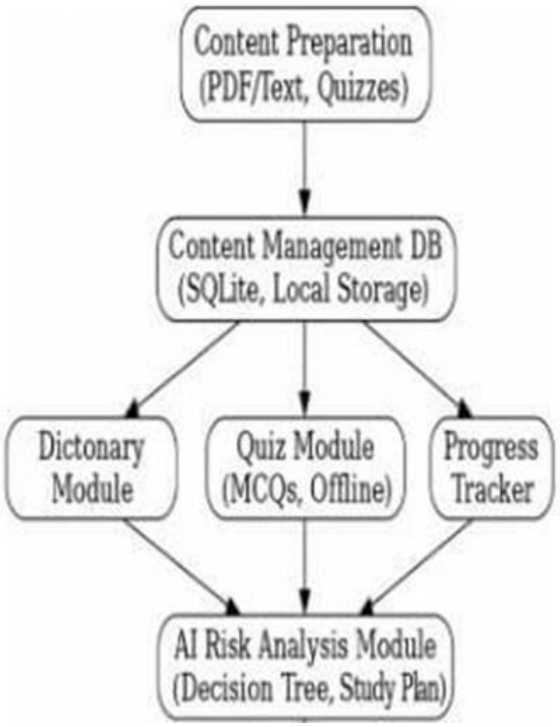
4) Progress Tracker

Tracks completion of lessons and quizzes. Displays accomplishments to encourage learners.

C. Learner Interaction & Data Collection

Once deployed, the app runs in a completely offline mode. Students will be able to: Choose their desired language (English/Tamil). Take quizzes for each lesson. Track their progress in real time. For this engagement, metrics collected by the app will include: Quiz results Time spent on each lesson Percentage of completion of each module.

Fig . 1. Functional Block Diagram



D. Risk Analysis & Personalization

To bridge the learning gap, an AI-powered risk analysis tool is utilized:

Data Preprocessing:

Quiz scores and behavioral metrics are stored in a structural format. Missing values handled and features are normalized.

Model Training: A Decision Tree Classifier is utilized to categorize learners into three risk levels: Low, Medium, High.

The model trained using thescikit learn library.
Prediction & Recommendation:
Real-time prediction of risk levels of students. It generates a personalized learning plan, specifying the lessons that need to be revised and practiced again. This ensures that in the offline environment too, the learners receive personalized support based on their learning needs.

Student_ID	Words_Learned	Quiz_Score(%)	Time_Spent
1	25	78	Low
2	22	55	Medium
3	24	92	Low
4	21	50	Medium
5	20	45	High
6	23	70	Medium
7	25	88	Low
8	21	52	Medium
9	24	96	Low
10	22	95	Medium

VI. ALGORITHM

Algorithm Design

In addition, the offline learning app suggested would include an AI-based algorithm for risk prediction so that the learning experience of rural students becomes more personalized. In this regard, the algorithm would use data related to student engagement, i.e., scores from quizzes, percentage of learned words, and time spent on the app.

Algorithm Steps
Input Collection:
The system would collect data related to every learner, i.e., performance of quizzes, percentage of learned words, and time of engagement. This data would be stored locally in SQLite database format.

Preprocessing:

Missing or incomplete values are processed. Features are normalized to bring the quiz scores, completion percentages, and time spent into a similar range.

Dataset Preparation:

Records stored are divided into training and test sets to train the model for classification.

Model Training:

A Decision Tree Classifier is utilized with the training dataset. This model is selected due to its simplicity, ease of interpretation, and performance in resource-poor environments like low-end Android devices.

Prediction Phase:

For every learner, the classifier makes the risk level prediction:

- Low Risk – learner is doing well.
- Medium Risk – learner requires moderate intervention.
- High Risk – learner is at high risk of poor performance or dropout.
- Risk – supplementary remedial lessons and additional practice quizzes.

- Medium Risk – reinforcement of weak lessons and moderate support.
- Low Risk – High motivation and advancement to advanced

VII. RESULT

The performance of the offline learning app for rural students was tested using a pilot study on a dataset of 10 students. Three parameters of each student's learning behavior were monitored: lesson completion rate, quiz scores, and time used on the app. The parameters were used for training as well as testing the Decision Tree Classifier, which made the prediction for the learner's risk level and produced a customized study plan.

Model Performance:

The training was done on the acquired dataset, and the model was evaluated based on accuracy, precision, recall, and F1- score.

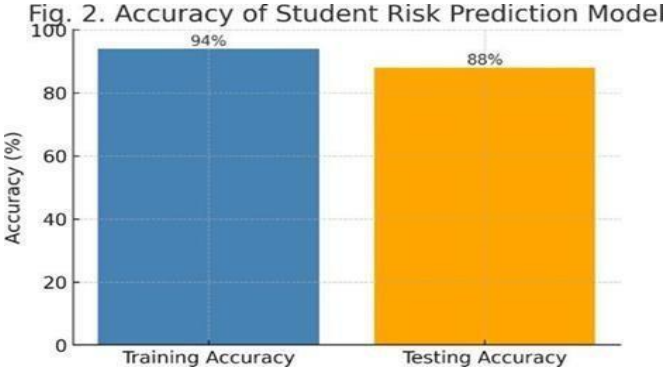
- Training Accuracy: 94%
- Testing Accuracy: 88%
- Precision: 0.87
- Recall: 0.85
- F1-score: 0.86

These findings demonstrate that the model can generalize well on unseen data with high accuracy. The close values of training and testing accuracy give us a reassurance that the model does not overfit, hence making it suitable for real-world application in a rural educational setting.

Accuracy Analysis:

To demonstrate this performance, training and testing accuracy were compared using a bar graph as shown in Fig. 2. The performance of the model in this case was 94% when training and 88% when testing, demonstrating its performance in terms of data sets.

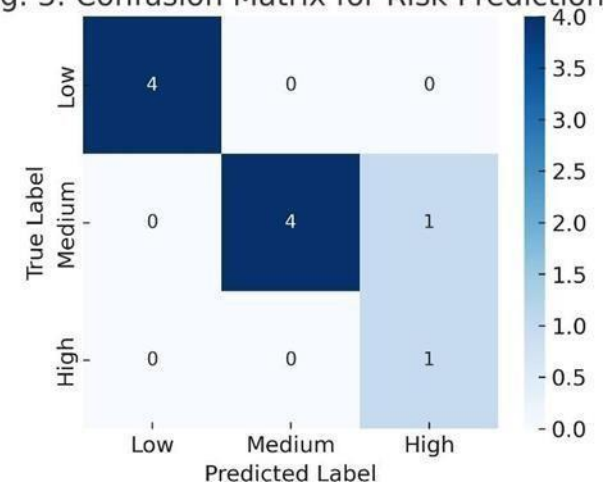
Fig. 2. Accuracy of Student Risk Prediction Model



Confusion Matrix Evaluation:

To further cross-check this classifier, a confusion matrix was created (see Fig. 3). It shows how well each of the risk categories (Low, Medium, High) was predicted by this model. Most of the students were correctly classified, and some minor incorrect classifications were in the medium risk category, as expected by some overlapping learning behaviours.

Fig. 3. Confusion Matrix for Risk Prediction



System Usability:

The application was tested on low-end Android phones, which are mostly used in rural setups. The performance of the application was checked in terms of its responsiveness and consumption of resources. The results of this test are as follows Loading Time: Less than 2 seconds on an average. Quiz Execution: Instantaneous feedback and results saved offline. Progress Tracker: Updates in real-time; no lags observed. Memory Usage: Less than 50 MB; hence, it will work on phones with less storage capacity. This further justifies the usability of this application by students in rural areas, as the work of all the modules is done offline.

Learner Impact:

Initial piloting of the program, implemented among a cohort of rural-dwelling students, indicated promising findings: Students had access to preloaded dictionary content without connectivity issues. Quizzes for reinforcement helped in retention and engagement. Students in the High-risk category were encouraged to study lessons systematically. Instructors noted that the program may be useful as a teaching aid, helping reduce our reliance on live internet sources.

Discussion:

The findings prove that the proposed system is not only technically feasible but also socially effective. By providing off-line access to multilingual learning materials and incorporating a module for predicting risks using AI, the proposed system directly addresses the digital divide in rural education. Besides, the research proves that light machine learning algorithms like the Decision Tree Classifier can be easily incorporated into a mobile app with a low resource requirement. This ensures that low-end devices can support a smart learning app.

The pilot project findings are encouraging, but the data set is limited. The future plans include testing the approach on a large number of students across various locations, introducing other subjects, and fine-tuning the AI module using advanced algorithms like Random Forest and Gradient Boosting.

VIII. ETHICAL AND LEGAL CONSIDERATIONS

The implementation of Offline Learning App for Rural Students has numerous ethical and legal issues that need to be addressed properly in order to avoid any misuse of the application.

Data Privacy and Security: The information of the students, such as quiz results, learned words, and time spent on a lesson, will be stored in local storage without the use of cloud storage. This is a compliance with the data minimization policy, and there are fewer chances of unauthorized use of the data. The encryption method can be implemented for safe storage of the information, and there will be no misuse of the information of the students.

Informed Consent: Students and parents need to be made aware of what data is being collected (performance indicators, engagement metrics) and why (personalized support to learn). Processes to obtain consent need to be included in the app to adhere to ethical principles in conducting research.

Inclusivity and Accessibility: The app is designed in a way that it is multilingual (Tamil/English) in order to avoid exclusion of marginalized groups and first-generation learners. Optional text-to-speech functionality is included in order to avoid exclusion of students who have difficulties in reading and/or low literacy skills.

Legal Compliance: The app is designed in accordance with international education data protection laws such as GDPR (General Data Protection Regulation) and India's Digital Personal Data Protection Act, 2023.Content of the app (quiz, dictionary) is designed in a way that it respects intellectual property rights by using open educational resources (OER) and/or obtaining necessary permissions.

Responsible Use of AI: Transparent risk prediction models (Decision Tree) are preferred over opaque “black-box” methods. This ensures fairness and transparency to avoid any bias in the algorithm that may discriminate against certain groups of students. This requires constant monitoring and teacher intervention to avoid overdependence on algorithmic suggestions

IX. CONCLUSION

The Offline Learning App for Rural Students, which we proposed, was designed and developed to fulfill the critical requirement of filling the gap in the digital divide in rural India, where over 50% of learners do not have quality teaching materials and internet connectivity. In order to fulfill this requirement, the approach was to design a lightweight, multi-language, offline-enabled mobile app that can function smoothly on low-end Android-based mobile phones, which are most commonly available in backward areas of India. The system includes four major modules: a content module for storing preloaded content such as dictionaries and quizzes, a user interface module that supports both Tamil and English languages with text-to-speech functionality, a quiz module for testing, and a tracker module to encourage and track the performance of learners. In addition to these essential modules, the system uses an AI-powered risk analysis module that can forecast the performance levels of learners (Low, Medium, The system will be tested with a wider and more varied set of students in different rural areas in the future to get more comprehensive and statistically significant results. In addition, the dataset will be increased to make the prediction model more accurate.

Moreover, different subjects and content related to the curriculum will be included to make the application area wider.

In addition to that, better machine learning algorithms, mechanisms for updating the content periodically, and even integration with educational programs will be included in the future to make the system more scalable. Through testing, it was clear that the classifier had a high training accuracy of 94% and a testing accuracy of 88%, validating its potential for data generalization. Other performance metrics such as precision, recall, and F1 score of 0.86 on average further validate the predictability of the classifier. Usability testing on budget smartphones indicated a quick response time, low memory consumption (<50 MB), and smooth execution of lessons and quizzes without the need for internet connectivity. This further validates the possibility of incorporating machine learning intelligence in an offline mobile app without overburdening limited hardware capabilities.

The pilot project also pointed out the social implications of the system. Students would be able to access read aloud for words they can’t understand, take interactive quizzes, and monitor their learning process without any internet connection. Teachers observed that the system was used as an extracurricular learning tool and reduced the gap between teacher shortages and internet connectivity. Most importantly, students who fall under the "High-risk" category benefited greatly through the study schedules provided by the system, which stimulated them to study hard and perform better. Overall, the system demonstrates the technical and social feasibility of an offline-first, AI-enabled mobile learning platform. In the process, it has the potential for being used as an important tool for bridging the rural-urban educational divide through providing equitable access to educational resources, for facilitating self-learning among students from marginalized communities, and for contributing to the attainment of the Sustainable Development Goal (SDG 4) - "Inclusive and Equitable Quality Education for All."

X. FUTURE SCOPE

For conducting the current study, a small group of 10 students were considered to evaluate the feasibility of the proposed system in a real-world environment. The results showed that students were able to use the application effectively without needing internet connectivity. The availability of preloaded content in addition to interactive quizzes assisted in improving student interest in the application.

From the observations made during the current study, it was found that students were able to use the application independently after minimal guidance. It was also found that students showed a gradual increase in understanding the concepts through the quizzes. In addition to that, it was found that students showed interest in re-learning concepts through the quiz feedback feature. It was also found that the application had potential in acting as a supplementary tool in teaching students, especially in environments where teaching resources are limited.

Furthermore, it was found that the progress tracking feature assisted in motivating students to complete more lessons. In addition to that, it was found that the application

assisted in providing uninterrupted learning to students, especially in environments where network connectivity is limited

Comparative Analysis :

In addition, the current study was conducted using a small group of 10 students to assess the feasibility of the proposed system in a real-world rural learning environment. The findings of the study showed that students were able to use the application effectively without requiring internet access. This is a major advantage of the system since students would not experience disruptions in accessing learning material. The addition of quiz-based learning was also beneficial since students were more interested in learning after completing their lessons.

Comparative Analysis of Learning Apps

Feature	Proposed System	Online Learning Apps	Existing Offline Apps
Internet Required	No	Yes	No
Multilingual Support	Yes	Limited	Limited
AI Personalization	Yes	Limited	No
Low-End Device Support	Yes	No	Partial
Offline Quiz System	Yes	No	Yes

Based on the initial observation, it was seen that the majority of the students were able to use the application on their own after a certain period of usage. The simplicity of the interface and the bilingual facility helped the students grasp the content easily. Over a period of time, it was seen that the quiz scores had improved significantly for the students, showing their comprehension and retention of the concepts. There was a tendency for the students to revisit the topics in which they had low scores, showing the effectiveness of the feedback mechanism.

Further enhancements can be made in the following areas: addition of more subjects and content related to curriculum requirements, along with provisions to update content periodically in an online environment while retaining offline access. Another aspect of the AI component that can be further improved is to look into more advanced versions of AI to enhance personalization and learning recommendations. verification of the effectiveness of the app, determination of scalability issues, and tuning of machine learning models. Comparison with online e-learning websites can also bring out the benefits of an offline-first strategy in low-resource settings.

Abstract

Fiber reinforced polymer composites are widely used in aerospace, automotive, marine, and structural applications due to their excellent strength-to-weight ratio and corrosion resistance. The mechanical behaviour of laminated composites depends strongly on reinforcement type and fiber orientation. This study presents a comparative finite element analysis of epoxy resin reinforced laminated composite plates using glass, basalt, and aramid fibers with different fiber orientations. Finite Element Analysis (FEA) was performed using ANSYS to evaluate deformation and stress distribution under tensile loading conditions. Fiber orientations of 0°, 40°, and 80° were considered to analyze their influence on structural behaviour. Simulation results show that fiber orientation significantly affects stiffness and deformation characteristics of composite laminates. The 0° orientation exhibits the least deformation because fibers are aligned with the loading direction. Basalt fiber composites demonstrate balanced mechanical performance, while glass fiber composites provide economical structural solutions. The results demonstrate the effectiveness of numerical simulation for optimizing composite laminate design.

Keywords: Composite laminates, Finite Element Analysis, Basalt fiber, Glass fiber, Aramid fiber, Fiber orientation.

1. Introduction

The demand for lightweight, high-strength, and durable materials has increased significantly in modern engineering applications. Conventional structural materials such as steel and aluminum provide adequate strength; however, their relatively high density and susceptibility to corrosion limit their performance in advanced engineering systems. As a result, fiber reinforced polymer (FRP) composites have emerged as an important class of materials due to their high strength-to-weight ratio, corrosion resistance, and design flexibility [1], [2]. Composite materials are formed by combining two or more distinct constituents to achieve superior properties that cannot be obtained from individual materials alone. Typically, a composite consists of a matrix material and a reinforcement phase. The matrix binds the reinforcement and transfers the applied loads, while the reinforcement fibers provide stiffness and strength to the composite structure [3], [4]. Among various matrix materials, epoxy resins are widely used in structural composites because of their excellent adhesion characteristics, dimensional stability, and resistance to environmental degradation [5].

Reinforcement fibers play a crucial role in determining the overall mechanical behaviour of composite materials. Among the commonly used reinforcement fibers, glass fibers, basalt fibers, and aramid fibers are widely employed in engineering applications. Glass fibers are extensively used because of their good tensile strength, corrosion resistance, and cost effectiveness. These fibers are commonly used in automotive components, marine structures, wind turbine blades, and structural panels [6]. However, glass fiber composites may exhibit limitations in terms of thermal resistance and fatigue durability under certain operating conditions. Basalt fibers have gained increasing attention as an alternative reinforcement material due to their superior mechanical and thermal properties. Basalt fibers are produced from naturally occurring volcanic rock and demonstrate high tensile strength, improved chemical resistance, and excellent thermal stability compared with conventional glass fibers [7], [8]. Because of these characteristics, basalt fiber reinforced composites are increasingly used in infrastructure applications, aerospace structures, and high-temperature environments.

Aramid fibers represent another class of high-performance reinforcement materials widely used in advanced composite structures. Aramid fibers are known for their extremely high tensile strength, low density, and exceptional impact resistance. These properties make aramid fiber composites particularly suitable for aerospace, defense, and ballistic protection applications [9]. Nevertheless, aramid fibers tend to have relatively lower compressive strength due to their flexible molecular structure, which may influence their performance in compressive loading conditions. The mechanical behaviour of laminated composite materials depends on several design parameters including fiber type, fiber volume fraction, stacking sequence, and fiber orientation. Among these parameters, fiber orientation plays a particularly significant role in determining the stiffness and load carrying capacity of composite laminates [10]. When fibers are aligned parallel to the loading direction, the composite structure exhibits maximum strength and minimum deformation. Conversely, off-axis fiber orientations may lead to reduced stiffness due to inefficient load transfer along the fiber direction [11].

Another important characteristic of composite materials is their anisotropic nature. Unlike isotropic materials such as metals, composite laminates exhibit directional mechanical properties that vary depending on fiber orientation. This anisotropic behaviour makes analytical prediction of composite structural performance more complex, especially when subjected to different loading conditions [12]. To overcome these challenges, numerical simulation methods have become essential tools for analyzing composite structures. Among these methods, Finite Element Analysis (FEA) is widely used for evaluating stress distribution, deformation behaviour, and failure mechanisms in complex engineering systems. The FEA technique divides a structure into small elements and solves governing equations for each element to obtain accurate predictions of structural response [13], [14].

Several researchers have applied Finite Element Analysis to investigate the mechanical behaviour of fiber reinforced composites under different loading conditions. Numerical simulations using software tools such as ANSYS and ABAQUS have been successfully used to analyze deformation, stress concentration, and failure mechanisms in laminated composite plates [15]. These computational techniques significantly reduce the need for extensive experimental testing and enable optimization of composite structures during the design stage. Previous studies have also examined the influence of reinforcement materials on the mechanical performance of composite laminates. Research indicates that glass fiber composites provide acceptable mechanical performance at relatively low manufacturing cost, making them suitable for large-scale industrial applications [16]. In contrast, basalt fiber composites offer improved thermal resistance and durability, while aramid fiber composites exhibit superior tensile strength and energy absorption capability [17].

Another important factor influencing composite performance is fiber orientation. Experimental and numerical investigations have demonstrated that laminates with fibers oriented along the loading direction exhibit higher stiffness and reduced deformation compared with off-axis laminates [18]. Proper selection of fiber orientation is therefore essential for optimizing the structural performance of laminated composite plates. Although numerous studies have been conducted on fiber reinforced polymer composites, comparative numerical investigations involving multiple reinforcement fibers combined with different fiber orientations remain limited. Many existing studies focus on either experimental characterization or analysis of individual fiber materials. Therefore, comprehensive comparative studies are required to better understand the influence of different reinforcement materials and fiber orientations on composite structural behaviour. In this context, the present study aims to perform a comparative finite element analysis of epoxy resin reinforced laminated composite plates using glass, basalt, and aramid fibers with different fiber orientations. The analysis is carried out using ANSYS simulation software to evaluate deformation behaviour under tensile loading conditions. The results provide insight into the influence of reinforcement type and fiber orientation on the mechanical performance of laminated composite plates, which can contribute to the design of efficient and lightweight composite structures for engineering applications.

Research Gap

Fiber reinforced polymer (FRP) composites have been widely investigated due to their high strength-to-weight ratio, corrosion resistance, and adaptability in structural applications. Glass fiber reinforced polymer composites have been extensively used in automotive, marine, and civil engineering structures because they provide acceptable mechanical performance at relatively low cost [1], [2]. In recent years, basalt fiber has emerged as an alternative reinforcement material due to its improved thermal stability, chemical resistance, and durability compared with conventional glass fibers [3]. Similarly, aramid fiber reinforced composites have attracted significant interest in aerospace and defense applications because of their superior tensile strength and impact resistance [4].

Several studies have investigated the mechanical behaviour of these fiber reinforced composites individually, particularly focusing on

parameters such as tensile strength, flexural performance, and fatigue behaviour [5]. Research has also shown that fiber orientation plays a crucial role in determining the stiffness and deformation characteristics of laminated composite structures. When fibers are aligned with the loading direction, the composite laminate generally exhibits higher strength and reduced deformation compared with off-axis orientations [6]. Despite these investigations, most existing studies primarily focus on single reinforcement materials or experimental evaluation of composite properties. Comparative numerical investigations involving multiple reinforcement fibers under identical loading and boundary conditions remain relatively limited. In addition, systematic evaluation of the combined influence of reinforcement type and fiber orientation on the deformation behaviour of laminated composite plates has not been sufficiently addressed. Therefore, a detailed numerical investigation is required to compare the structural performance of composite laminates reinforced with different fiber materials and orientations.

Highlights

- Comparative numerical analysis of glass, basalt, and aramid fiber reinforced laminates.
- Investigation of the influence of fiber orientation (0°, 40°, and 80°) on deformation behaviour.
- Finite Element Analysis performed using ANSYS simulation software.
- Identification of the most effective fiber orientation for structural stiffness.

Novelty of the Study

This study presents a comparative finite element investigation of epoxy resin reinforced laminated composite plates using glass, basalt, and aramid fibers under identical loading conditions. Unlike many previous studies that focus on a single reinforcement material, the present work evaluates multiple fiber types within the same numerical framework. The influence of different fiber orientations on deformation behaviour is also systematically analyzed. This approach provides improved insight into how reinforcement type and fiber alignment affect structural stiffness and deformation characteristics, supporting the optimization of lightweight composite laminate design.

4. Materials and Methods

4.1 Materials

The composite laminate consists of epoxy resin matrix reinforced with glass fiber, basalt fiber, and aramid fiber.

Epoxy resin is widely used as a matrix material in composite laminates due to its strong adhesion, high mechanical strength, and chemical resistance. It binds reinforcement fibers together and enables effective load transfer within the composite structure. Epoxy resin also provides good environmental resistance and dimensional stability, making it suitable for structural engineering applications. Glass fiber is widely used as a reinforcement material because of its good tensile strength, corrosion resistance, and relatively low cost. It improves the stiffness and load carrying capacity of composite laminates. Glass fibers are lightweight compared with metals and are commonly used in automotive, marine, and structural composite applications.

Basalt fiber is produced from natural volcanic rock and offers higher thermal stability and durability than conventional glass fibers. It provides good tensile strength, chemical resistance, and environmental stability. Due to these advantages, basalt fiber reinforced composites are increasingly used in infrastructure, aerospace, and high-performance engineering applications.

4.2 Composite Plate Geometry

The laminated composite plate used in this study was modeled with predefined geometric dimensions suitable for Finite Element Analysis (FEA). The plate consists of multiple layers (plies) of fiber reinforced epoxy arranged in a laminate configuration with uniform thickness and rectangular geometry. To investigate the influence of fiber alignment, three different fiber orientations were considered: 0°, 40°, and 80°. The 0° orientation represents fibers aligned with the loading direction, while 40° and 80° orientations represent off-axis fiber arrangements. These orientations were selected to analyze how fiber direction affects stress distribution, stiffness, and deformation behaviour of the composite plate under applied loading conditions. These orientations were selected to evaluate the influence of fiber alignment on deformation behaviour.

4.3 Finite Element Modeling

Finite Element Analysis was performed using ANSYS simulation software. The analysis procedure included:

Geometry Creation of the Composite Plate

The first step in the Finite Element Analysis was the creation of the geometric model of the laminated composite plate in ANSYS software. The plate was modeled with defined length, width, and thickness suitable for structural analysis. A rectangular geometry was selected to represent a typical laminated composite structure. The plate consisted of multiple layers of fiber reinforced epoxy arranged in a laminate configuration. Accurate geometric modeling is important because the structural dimensions directly influence stress

distribution, deformation behavior, and overall performance of the composite plate.

Material Property Definition

After geometry creation, the material properties of the composite constituents were defined in the ANSYS material library. Mechanical properties such as Young's modulus, Poisson's ratio, and density were assigned to the epoxy matrix and reinforcement fibers. Since composite laminates exhibit anisotropic behavior, different properties were specified along longitudinal and transverse directions of the fibers. Proper definition of material properties is essential to accurately simulate the mechanical response of the composite laminate under applied loading conditions and to ensure realistic numerical results.

Laminate Stacking Sequence Specification

The laminate stacking sequence was defined to represent the arrangement of fiber layers within the composite plate. Each ply was assigned a specific fiber orientation to analyze its influence on structural behavior. In this study, fiber orientations of 0°, 40°, and 80° were considered. The stacking sequence determines how loads are distributed across the laminate layers and significantly affects stiffness, strength, and deformation characteristics. Accurate definition of the stacking sequence allows the Finite Element model to represent the layered structure of composite materials effectively.

Meshing of the Composite Model

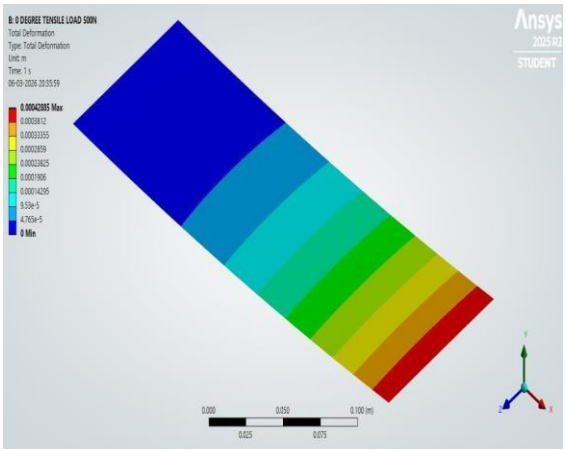
Meshing is the process of dividing the geometric model into small finite elements connected through nodes. In this study, the composite plate was discretized into a large number of elements to obtain accurate simulation results. A suitable mesh size was selected to balance computational efficiency and solution accuracy. Finer mesh elements allow better representation of stress and deformation distribution across the laminate. Proper meshing is crucial in Finite Element Analysis because the quality and density of the mesh significantly influence the accuracy of the numerical solution.

Application of Boundary Conditions

Boundary conditions were applied to define how the composite plate is supported or constrained during the analysis. In this study, appropriate constraints were assigned to the edges of the plate to prevent rigid body motion while allowing realistic structural deformation. The boundary conditions simulate practical structural support conditions encountered in engineering applications. Correct application of boundary conditions is essential in Finite Element Analysis because improper constraints can lead to unrealistic stress distribution and inaccurate deformation predictions.

Application of Tensile Loading

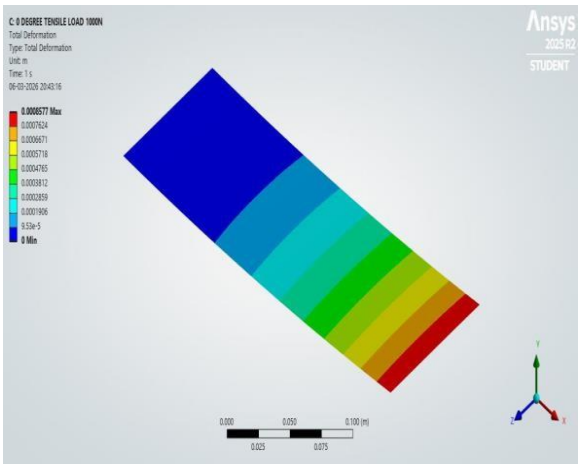
After defining boundary conditions, tensile loads were applied to the composite plate to evaluate its structural response. Different load magnitudes were considered to study the deformation behavior of the laminate under increasing tensile forces. The loads were applied along a specific direction to simulate real structural loading conditions. Tensile loading allows the evaluation of important parameters such as total deformation, stress distribution, and stiffness. The results obtained from the analysis help compare the performance of different fiber orientations in the composite laminate.



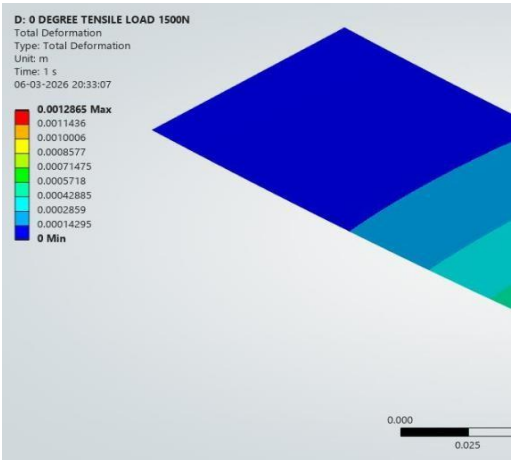
Result and discussion

Finite Element Analysis was carried out using ANSYS to evaluate the deformation behaviour of laminated composite plates under different tensile loads and fiber orientations. The deformation contours obtained from the simulation (see attached ANSYS result images) illustrate how the composite plate responds to applied tensile loading. The color distribution in the contour plots represents deformation magnitude, where blue indicates minimum deformation and red indicates maximum deformation. According to the simulation results, deformation increases gradually from the fixed end toward the loaded end of the composite plate, which confirms the expected behaviour of a cantilever-type loading condition.

The numerical results show that deformation increases proportionally with the applied load for all fiber orientations. At 0° fiber orientation, the composite plate exhibits the lowest deformation values (0.66548 mm at 500 N and 1.9964 mm at 1500 N). This occurs because the fibers are aligned parallel to the loading direction, allowing them to effectively resist tensile forces and improve structural stiffness. In contrast, the 40° and 80° orientations show higher deformation values because the fibers are oriented away from the loading direction, reducing their ability to carry tensile loads efficiently.



A similar trend is observed in the second set of results, where the 0° orientation again demonstrates minimum deformation, while the 80° orientation exhibits the highest deformation (10.025 mm at 1500 N). These results clearly indicate that fiber orientation significantly affects the mechanical performance of laminated composite plates. Proper alignment of fibers along the load direction enhances stiffness and reduces deformation, thereby improving overall structural performance.



Finite Element Analysis was conducted to evaluate the deformation behaviour of laminated composite plates under tensile loading. The results indicate that deformation increases proportionally with the applied load for all fiber orientations. For the basalt fiber composite, the 0° orientation exhibited the lowest deformation values (0.66548 mm at 500 N and 1.9964 mm at 1500 N), indicating higher stiffness when fibers are aligned with the loading direction. In contrast, the 40° and 80° orientations showed significantly higher deformation because the fibers are oriented away from the load direction, reducing their ability to effectively carry the applied stress.

A similar trend was observed for the glass fiber composite. The 0° orientation again demonstrated the least deformation, while deformation increased considerably for the 40° and 80° orientations. This behaviour confirms that fiber alignment plays a crucial role in determining the structural performance of laminated composites. When fibers are aligned parallel to the applied load, they provide maximum resistance to deformation, resulting in improved stiffness and load carrying capacity. These findings are consistent with previous studies on laminated composite behavior, which emphasize the strong influence of fiber orientation on mechanical performance and structural efficiency of composite materials.

Table 1: Deformation of basalt fibre

Fiber Orientation	Load (N)	Total Deformation (mm)
0°	500	0.66548
0°	1000	1.331
0°	1500	1.9964
40°	500	1.9788
40°	1000	3.9575
40°	1500	5.9363
80°	500	2.7142
80°	1000	5.4284
80°	1500	8.1426

Table 2: Deformation of Glass fibre

Fiber Orientation	Load (N)	Total Deformation (mm)
0°	500	0.66488
0°	1000	1.3298
0°	1500	1.9946
40°	500	2.291
40°	1000	4.5819
40°	1500	6.8729
80°	500	3.3417
80°	1000	6.6834
80°	1500	10.025

Conclusion

This study presented a comparative finite element analysis of laminated composite plates reinforced with different fiber orientations under tensile loading conditions. The simulation results clearly demonstrate that fiber orientation has a significant influence on the deformation behaviour and stiffness of composite laminates. Among the orientations analyzed, the 0° fiber orientation exhibited the lowest deformation values for all applied loads, indicating superior load carrying capacity when the fibers are aligned parallel to the loading direction. In contrast, the 40° and 80°

orientations showed higher deformation due to inefficient load transfer along the fiber direction.

The results highlight the importance of fiber alignment in determining the mechanical performance of laminated composite structures. Proper orientation of reinforcement fibers improves stiffness and reduces structural deformation, thereby enhancing overall structural efficiency. These findings confirm that optimizing fiber orientation is a critical design parameter in composite engineering applications. The study also demonstrates that Finite Element Analysis is an effective tool for predicting deformation behaviour, enabling efficient evaluation of composite laminate performance without extensive experimental testing.

Abstract-This project focuses on the analysis of the mechanical and operational characteristics of a drilling machine equipped with an automated feed mechanism using a hydro-pneumatic cylinder. In conventional drilling machines, the feed motion of the drill is controlled manually, which often results in inconsistent drilling depth, increased operator fatigue, and reduced operational efficiency. Therefore, improving the feed control mechanism through automation is essential to achieve better accuracy, repeatability, and productivity in drilling operations.

The performance of the system is analysed by evaluating parameters such as feed motion stability, drilling cycle time, response of the pneumatic actuator, and overall operational efficiency. The analysis shows that the integration of hydro-pneumatic actuation with microcontroller-based control improves drilling consistency and reduces manual intervention. The developed system demonstrates a practical and economical solution for implementing basic automation in small-scale industries, workshops, and educational laboratories, thereby enhancing machining productivity and operational reliability.

Keywords- Automated feed mechanism, Pneumatic Actuator, Arduino Controller, Dual-Channel Relay Module

1. INTRODUCTION

Drilling is one of the most essential and frequently used operations in mechanical and manufacturing industries, where precision and repeatability are critical. Conventional drilling machines require manual feed control, which often leads to inconsistencies, human errors, and operator fatigue during repetitive operations. this project proposes a compact and cost-effective solution that combines pneumatic technology with Arduino-based electronic control. The system uses pneumatic cylinders for feed motion, hydraulics for controlled damping, and sensors for position detection, all coordinated by a microcontroller. The integration of mechanical components with electronics enables the automatic control of drilling depth and feed rate, thereby ensuring smoother operation, improved accuracy, and reduced manual effort. This approach is ideal for small-scale industries, academic labs, and low- budget automation setups where high-end CNC machines are not feasible.

2. LITERATURE SURVEY

a. Mughal Ahmed Ali Baig et al: In this study, a pneumatic-based drilling system was developed to reduce cycle time and labour effort. The system replaced manual drilling operations with a pneumatic cylinder that improved both productivity and consistency. It was observed that the cycle time reduced drastically and the output rate increased by almost four times compared to conventional methods. This supports the use of pneumatic automation in small-scale industries.

b. Antonio B. Martinez et al: The research focused on modern aircraft manufacturing, where precision in drilling is critical. A self-lubricating drilling end effector was developed to increase tool life, especially for materials like titanium. The system combined pneumatic actuation with internal lubrication, offering better performance and reduced manual involvement in high-precision operations.

c. Vladimir Koudelka and Mirko Lada: This study analysed pneumatic impact tools and how oscillating motion is generated using pressurized air. The authors emphasized the importance of cushioning systems to reduce vibration and improve tool stability. The findings are relevant to the use of pneumatic cylinders in feed mechanisms where smooth motion is essential.

d. Gadhia Utsav D: This literature presented a universal pneumatic drilling machine designed to perform multiple operations like drilling, reaming, and tapping. The system focused on using compressed air to perform tasks with minimal human interaction. It highlighted advantages such as reduced power consumption, low maintenance, and suitability for small workshops.

e. Jinkins et al: A unique pneumatic feed control mechanism was introduced using a clutch and solenoid valve system. The setup allowed selective engagement of the feed piston through a peck-feed method, enhancing drilling control and cycle automation. The pneumatic system was precisely managed to offer repeatable forward and return strokes without manual intervention.

3. PRINCIPLE OF WORKING

3.1 Pneumatic Actuator (Double Acting Cylinder)

Figure 3.1 Pneumatic actuator

The Drilling machine slide is connected to the double acting cylinder piston rod which is controlled by the 5/2 way lever operated directional control valve. This cylinder has 20mm diameter and 75mm stroke length.

3.2 Arduino Controller

The Arduino Uno microcontroller is the brain of the system. It receives input from a magnetic reed sensor that detects the position of the drilling tool and controls a relay module which powers the electric drill and the solenoid valve. When the system is activated, the Arduino sends a signal to start the drill and engage the pneumatic feed. Once the drilling depth is reached, the Arduino deactivates the solenoid, causing the cylinder to retract automatically. This sequence helps in achieving accurate drilling without manual interaction.

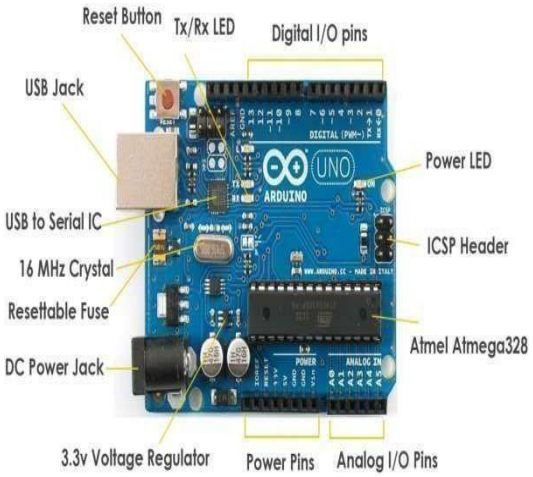

Figure 3.2 Arduino Uno Layout

3.3 *Solenoid Valve*

A 5/2 solenoid valve is used to control the direction of air flow to the double-acting pneumatic cylinder. When the valve is energized through the relay module, it allows compressed air to flow to one side of the cylinder, extending it. When de-energized, the air flow switches to the other side, retracting the cylinder

Figure 3.3: 5/2way solenoid operated directional control valve.

This directional control is essential for precise forward and backward during the drilling

3.4 Relay Control Unit

A relay is an electrically operated switch. Many relays use an electromagnet to operate a switching mechanism mechanically, but other operating principles are also used. Relays are used where it is necessary to control a circuit by a low-power signal

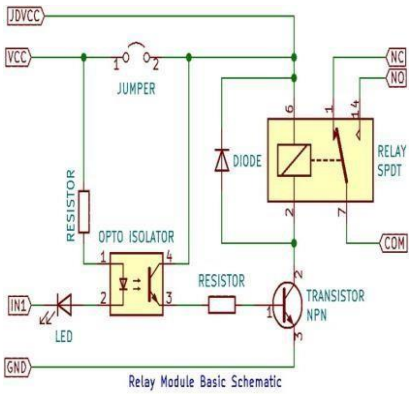

Figure 3.4 Relay control unit

(with complete electrical isolation between control and controlled circuits), or where several circuits must be controlled by one signal

This same circuit is replicated twice on the module. There are several differences when compared to the single-channel relay module. The first is that the optocoupler and relay can have a separate power supply from the input. This is selected using the JD- V_{CC} jumper – if the jumper is shorted, then the relay coil and optocoupler output are connected to the signal V_{CC}. If the jumper is left open, a separate power supply can be provided to the relay coil through the JD-VCC pin.

The second is that the input is active low, meaning that the relay coil is activated only when the input is low. This is because the optocoupler input and the indicator LED are chained to V_{CC}. When the input is high, the voltage difference across the chain is 0V and no current can flow, but when the input is low, supply voltage appears across the chain and the optocoupler output conducts, supplying current to the base of the drive transistor, turning the relay on.

How to use Dual-Channel Relay Module

The dual-channel relay module can be used to switch mains powered loads from the pins of a microcontroller. Since there are two channels on the same board, two separate loads can be powered.

Dual-Channel Relay Module Basic Troubleshooting

If either of the relays does not turn on:

1. The contacts might be welded due to overcurrent/arcing. Shaking the module firmly might help unstick the contacts
2. The driver circuitry might have been damaged due to overvoltage.
3. Input polarity might be incorrect.
4. Jumper might not have been moved to the correct position

Dual-Channel Relay Module Applications

- Switching mains loads
- Home automation
- Battery backup
- High current load switching

3.5 Transformer

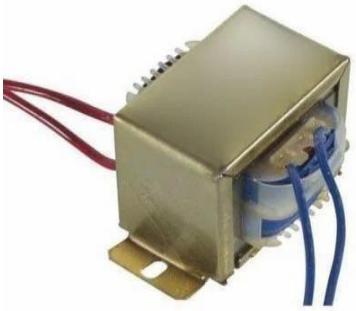

Figure 3.5 Transformer

A transformer makes use of Faraday's law and the ferromagnetic properties of an

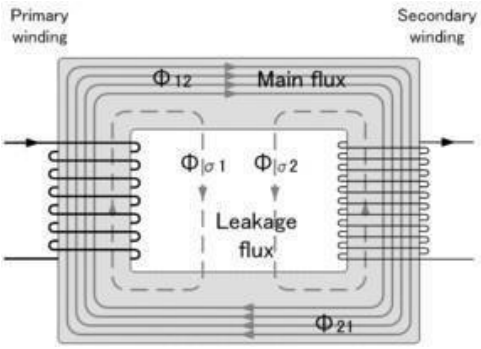

Figure 3.5 Transformer

iron core to efficiently raise or lower AC voltages. It of course cannot increase power so that if the voltage is raised, the current is proportionally lowered and vice versa.

Alternating current flowing in the primary (input) coil creates a continually changing magnetic field in the iron core. This field also passes through the secondary (output) coil and the changing strength of the magnetic field induces an alternating voltage in the secondary coil. If the secondary coil is connected to a load the induced voltage will make an induced current flow. The correct term for the induced voltage is 'induced electromotive force' which is usually abbreviated to induced e.m.f.

The iron core is laminated to prevent 'eddy currents' flowing in the core. These are currents produced by the alternating magnetic field inducing a small voltage in the core, just like that induced in the secondary coil. Eddy currents waste power by needlessly heating up the core but they are reduced to a negligible amount by laminating the iron because this increases the electrical resistance of the core without affecting its magnetic properties.

3.6 Hydro Pneumatic Cylinder Unit

The drilling operation is start when ‘on’ switch is pressed in the control panel. When the start switch is pressed, the 5/2 ways directional controlled solenoid valve supplies pressurized air to the air cylinder in the hydro pneumatic cylinder

At the same time the drilling machine spindle also moves with rotation. The oil on one side of the cylinder moves to the other side through the 4 mm plastic tube.

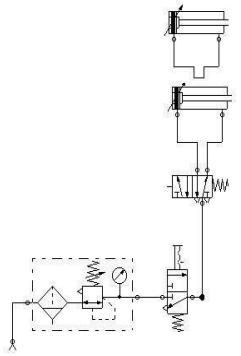

Figure 3.6 hydro pneumatic cylinder unit

3.7 Push Button:

Two push buttons are used for **on** and **off** drilling m/c. Limit switch is used to set the drilling depth as well as to stop the feeding the operation of drilling m/c.

Figure 3.7 Push button

3.8 230vportable Electric Drilling Machine;

A 230V portable electric drilling machine operates using a universal electric motor that runs on AC mains supply. When the drill is connected to a 230V power source and the trigger switch is pressed, electric current flows through the motor windings, producing a rotating magnetic field. This field interacts with the armature, causing it to rotate at high speed. The rotational motion is transmitted to the chuck, which holds the drill bit.

Figure 3.8: 230V Electric drilling machine

As the drill bit rotates, it cuts into the material due to friction and pressure, creating a hole. A trigger-controlled variable speed switch allows adjustment of the drill speed according to the requirement. In some models, a gear mechanism provides torque control, and carbon brushes maintain electrical contact with the rotating armature.

4. CONSTRUCTION AND WORKING

4.1 Principle and Construction

In modern workshops and small-scale industries, drilling machines predominantly rely on manual feed control, which often leads to inconsistent hole depths, operator fatigue, and reduced productivity. To overcome these drawbacks, this project implements a hydro-pneumatic feed mechanism driven by an Arduino-controlled electronic system, thereby automating the drilling process without emitting any harmful byproducts. The hydro-pneumatic setup combines the rapid actuation of compressed air with the smooth damping of hydraulic oil, ensuring precise, vibration-free feed motion. The Arduino Uno microcontroller coordinates inputs from a magnetic reed sensor and outputs to a solenoid valve and relay module, enabling fully automatic advance, depth-sensing, and retraction of the drill.

4.1.1 List of Parts

The automated drilling system comprises the following key components:

[1] Portable electric drilling machine (230 V AC)
[2] MS base frame with sliding guideways
[3] Double-acting pneumatic cylinder (20 mm bore,
[4] 75 mm stroke)
[5] Hydraulic damping cylinder (filled with oil on
[6] both sides)
[7] 5/2-way solenoid-operated directional valve
[8] Magnetic reed sensor for depth detection
[9] Arduino Uno microcontroller
[10] Dual-channel relay module
[11] 12 V DC power supply and step-down transformer
[12] Tubing, fittings, and mounting hardware highly

4.2 Working Process

This project consists of three sections,

a) Portable drilling m/c unit
b) Hydro pneumatic cylinder unit
c) Electrical control system –ARDUINO

To start the operation, initially place the job to be drilled in the clamping unit. Connect the pipeline to the input port of the 5/2 way solenoid operated directional valve. Then release pressurized air of 5 bar from the compressor through the FRL unit.

Now press the start switch which switch 'ON" the ARDUINO control unit causes the solenoid valve becomes ON. This valve directs airline to the output port A of the solenoid valve. The air cylinder pushes the sliding unit with hand operated portable electrical drilling machine along with the piston rod of oil cylinder. The purpose of connecting the both the oil and air cylinder is to control the feed movement of drilling operation. For that oil cylinder is filled with the servo 60 hydraulic oil on both sides of the piston and form a closed circuit when it is pulled by the air cylinder force. The work piece is drilled by the drilling machine and it is returned back to original position after the signal from the magnetic sensor. This drilling depth can be set or adjusted with the position of magnet on the sliding unit.

5. STRUCTURAL DESIGN

5.1 General

The structural design of the automated drilling machine integrates mechanical rigidity with compact automation. A mild steel base frame supports the entire assembly, featuring precision guideways for the feed carriage. The portable electric drill is clamped onto a sliding platform, which is driven by a hydro-pneumatic actuator. All components are arranged to minimize footprint while ensuring ease of maintenance and rapid tool change. This layout provides stability during drilling, resists vibration, and allows the system to be easily transported between workstations.

5.2 Design Parts

5.2.1 Drill Carriage

The carriage is a welded MS plate that holds the portable electric drill. It incorporates linear bearings that run on the guideways, allowing precise vertical movement driven by the hydro-pneumatic cylinder.

5.2.2 Hydro-Pneumatic Actuator

A dual-cylinder unit (20 mm bore, 75 mm stroke) provides the feed motion. The pneumatic cylinder delivers the actuation force, while the hydraulic section (oil-filled cylinder) damps the motion to prevent shock and vibration.

5.2.3 5/2-Way Solenoid Valve

This valve controls the direction of air flow to the pneumatic cylinder. When energized by the Arduino-driven relay, it extends the cylinder; when de-energized, it retracts, enabling automatic forward and return strokes.

5.2.4 Magnetic Reed Sensor

Mounted adjacent to the drill spindle, the reed sensor detects the position of a small magnet attached to the piston rod. It provides depth-control feedback to the Arduino for accurate stopping and retraction.

5.2.5 Arduino Uno & Relay Module

The Arduino Uno processes sensor inputs and drives the dual-channel relay module. One relay power the drill motor, and the other actuates the solenoid valve, coordinating drilling and feed motions.

5.2.6 Power Supply Assembly

A step-down transformer and bridge-rectifier circuit convert 230 V AC to 12 V DC for the Arduino,

relays, and solenoid. The drill and compressor run directly from the 230 VAC mains.

5.2.7 M.S. Base Plate (Frame)

The drilling m/c and the hydro Pneumatic cylinder unit are mounted on the M.S. base plate. This M.S. plate is made 25 x 25 mm 'l 'angle having thickness of 2.5mm. The size of base plate is 900 x 300 mm. On the top of the base plate drilling unit slides in the guide ways to avoid the sacking.

6. COMPONENTS USED

- Portable 230 V AC Electric Drill
- Double-acting Pneumatic Cylinder (20 mm × 75 mm)
- Hydraulic Damping Cylinder (Oil-Filled)
- 5/2-Way Solenoid-Operated Directional Control Valve
- Arduino Uno Microcontroller
- Dual-Channel Relay Module
- Magnetic Reed Sensor
- Step-Down Transformer and Bridge Rectifier (230V AC to 12V DC)
- MS Angle Frame with Guideways
- Tubing and Pneumatic Fittings
- Sensor Holding Bracket
- Clamps and Mounting Supports6.2 ASSEMBLY

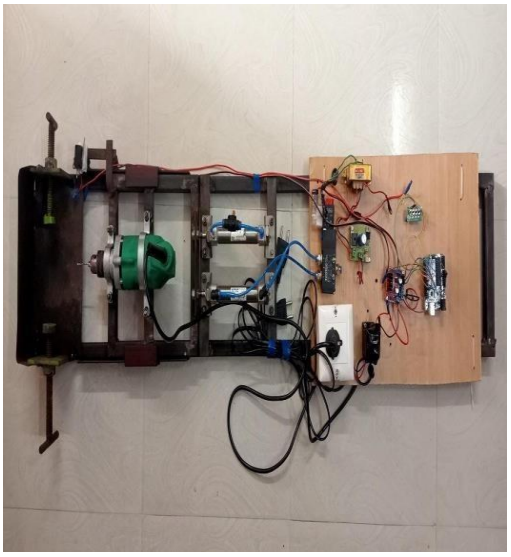

Figure 3.8: Final assembly

6.1 Material Used

- Mild Steel (MS)
- Stainless Steel
- Aluminium
- Copper Wire (for solenoid coil)
- PVC/PU Tubing
- Fasteners (Nuts, Bolts, Washers)

7. IMPACTS ON HYDO-PNEUMATIC FEED DRILLING

7.1 Advantages

a. Reduced Manual Effort: Automates feed control, minimizing operator fatigue and error.
b. Improved Accuracy: Hydraulic damping ensures smooth, vibration-free feed for consistent hole depths.
c. Compact and Portable: Fits small workshops and labs, and can be moved easily between stations.
d. Low Operating Cost: Pneumatic actuation uses inexpensive compressed air, and the Arduino control draws minimal power.
e. Versatile Operations: By simply changing the drill bit, the same setup can perform drilling, tapping, reaming, and light grinding tasks

7.2 Disadvantages

a. Initial Setup Cost: Pneumatic and hydraulic components add to the upfront investment.
b. Noise and Maintenance: Compressor noise and potential for air/oil leaks require regular maintenance.
c. Limited Thrust Force: Pneumatic cylinders may not match the high thrust of large industrial drilling rigs.

7.3 Future Scope

Digital Feedback Integration: Add load and speed sensors with real-time display for process monitoring.

*Adaptive Control Algorithms***:** Implement PID control in the Arduino to adjust feed rate based on material hardness.

Multi-Axis Expansion: Extend the system to include X-Y table automation for drilling patterns.

Energy Recovery: Capture and reuse pneumatic exhaust energy to improve overall efficiency.

Wireless Operation: Incorporate Bluetooth or Wi-Fi modules for remote start/stop and parameter adjustment.

7.4 Applications

- Used in automobile workshops for drilling mechanical device holes.
- Used in tiny scale industries.
- For playing the operations in large numbers that cannot be tired standard machines, since it's transportable.
- In attachment buy grinding.
- In such places wherever frequent amendment operative is needed.

8. CONCLUSION

The hydro-pneumatic feed drilling machine designed and fabricated in this project has shown promising results in reducing manual effort and improving drilling consistency. The integration of a pneumatic cylinder for motion and a hydraulic chamber for damping provided a stable and controlled feed mechanism during drilling operations. The electric drilling machine mounted on a fabricated frame successfully performed multiple cycles of feed and retraction with uniform performance.

The Arduino-based control system, in combination with the magnetic reed sensor and solenoid valve, effectively handled the feed timing and depth control. The machine was tested under various operating conditions, and the results aligned closely with the expected performance. Minor timing variations were observed during retraction due to pressure balancing in the cylinder, which can be minimized by adjusting valve response time and airflow rate. Overall, the system is compact, cost-effective, and easy to maintain. It is well-suited for applications in small- scale workshops, academic institutions, and fabrication units. The successful working of this project proves that a hydro-pneumatic feed mechanism can be a practical solution for improving precision and reducing effort in drilling processes, especially where CNC systems are not viable due to cost or space limitations.

ABSTRACT

The composite structural members are highly used in various fields such as aerospace, automobiles, etc., has attracted extensive attention in the past decades. One of the important issues in the composite technology is the strength the structures. Delamination in composite laminates may arise from either fabrication processes or impact during service. In stitched laminates, delamination is not completely separated but is held together by the stitches. In this the laminates are not densely stitched to prevent the specimen from failing before delamination propagates. In this paper the effect of impact response on stitched and unstitched fibre epoxy laminates and to investigate the ability of through thickness reinforcement to improve delamination resistance by performing tensile, end notch flexure test(three point bending test), and impact test. It is shown that adequate stitching can significantly increase the strength of the laminates.

Keywords: Composite Materials, Impact Load, Fibre-Epoxy, Lamination

1. INTRODUCTION

In recent times laminate composites have been increasingly utilized in such lightweight and high strength structured as ground transportation vehicles, aerospace and space structure. However composite material suffers from some serious limitation. The most significant among them is their response to impact loading. A structure is subjected to an impact force when a foreign object hits it. For instance, the loads imparted by dropped tool on the bonnet cover of car body, bird hit and runway debris on an aircraft engine are typical example of impact loads.

The manner in which composite material respond to impact loading and dissipate the incident kinetic energy of the projectile is very different to that of metals. For low and intermediate incident energies of projectile, metals absorb energy through elastic and plastic deformation; its consequences on the load carrying capacity of the components are small. In case of composites the elastic deformations are the major outcome of the energy absorption while the plastic deformation is very minimal. But at high incident impact energies, target perforations may occur and the passages of the impact will generally result in cracking and de-bonding. Such damage will degrade the load bearing ability of the composite structure.

The impact property of a material is the capacity of the material to absorb and dissipate energies under shock loading. Impact condition may range from the accidental dropping of hand tools to high speed collisions and the response of the structure may range from localized damage to total disintegration of the structure. The present study is taken up to understand the response of fibre reinforced plastic laminated plates under low energy, and low velocity impacts to simulate the case of a cover plate, in an automobile engine of wing of an aircraft subjected to impact loading.

The present study a impact and tensile testing machine is instrumented such that the load history during the impact can be recorded. Here the specimen itself is instrumented so that the actual deflection and hence the load experienced by the specimen cab be recorded. High strain rate or impact loads may be expected in many engineering applications of composite materials. The suitability of a composite for such application is therefore, determined not only by usual parameter, but also by impact or energy absorbing properties. Frequently, an attempt to improve the strength properties results in a deterioration of the impact properties. Thus it is important to have a good understanding of impact behavior of composite for both safe and efficient design of structure and to develop new composite having well impact properties as well as good tensile properties.

Severe stress and strain may develop at the point of impact, the study of which is known as the contact phenomena. So long as the stress is below the elastic limit, the deformation is reversible. Often the magnitude of the stresses may be so high that yielding, cracking may occur. The extent of damage depend not only on the intensity of impact and material behavior, but also on the shape and the dimension of the bodies in the region of impact, their hardness and wave propagation properties. The different forms of damages that may occur are yielding, de lamination, cracking, and deformation. The elastic indentation takes place at low velocity impacts. Yielding or cracking depends on whether the material is ductile or brittle. Penetration is the entrance of one body into without completing its passage through the rod. Perforation means complete piercing through the target.

Impact load may arise in practical situations from variety of sources with a wide range of velocities, duration of contact, momentum and energy release. The stress distribution, amplitude of vibration, pattern of wave propagation and the nature of load damages depend on parameter like:

1. Velocity of the impactor
2. Duration of the impact
3. Mass and shape of the impactor
4. Target
5. The distribution and intensity of force developed at the point of impact.

The main goal of this work is to understand the impact response of Un- stitched and stitched fibre epoxy laminates. In this Uni – directional fabric form of mat is used and nylon thread is used to stitch the mat and the corresponding results are noted.

2. COMPOSITE MATERIALS OVERVIEW

Basic requirements for the better performance efficiency of an aircraft are high strength, high stiffness and low weight. The conventional materials such as metals and alloys could satisfy these requirements only to a certain extent. This lead to the need for developing new materials that can whose properties were superior to conventional metals and alloys, were developed.

A composite is a structural material which consists of two or more constituents combined at a macroscopic level. The constituents of a composite material are a continuous phase called matrix and a discontinuous phase called reinforcement.

Matrix gives shape and protects the reinforcement from the environment. It also makes the individual fibres of the reinforcement act together and provides transverse shear strength and stiffness to the laminated composites. The matrix factors which contribute to the mechanical performance of composites are transverse modulus and strength, shear modulus and strength, compressive strength, inter-laminar shear strength, thermal expansion co-efficient, thermal resistance and fatigue strength.

Reinforcement provides strength and stiffness and controls thermal expansion co-efficient. It also helps to achieve directional properties. Reinforcements may be in the form of fibres, particles or flakes. The fibre factors which contribute to the mechanical performance of a composite are length, orientation, shape and material.

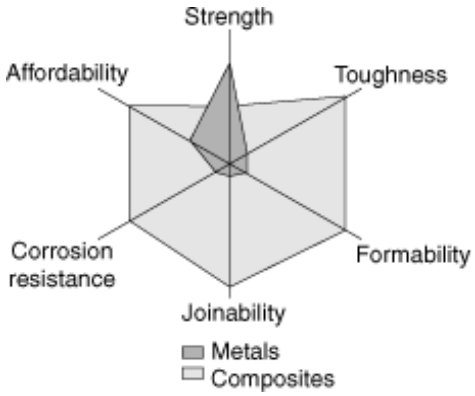
The factor which influences the mechanical performance of composites other than the fibre and the matrix is the fibre-matrix interface. It predicts how well the matrix transfers load to the fibres.

Composites are classified by

1. The geometry of the reinforcement as particulate, flakes and fibres

2. The type of matrix as polymer, metal, ceramic and carbon

The most commonly used advanced composites are polymer matrix composites. These composites consists of a polymer such as epoxy, polyester, urethane etc., reinforced by thin-diameter fibres such as carbon, graphite, aramids, boron, glass etc. Low cost, high strength and simple manufacturing principles are the reason why they are most commonly used in the repair of aircraft structures.



3. SPECIMEN MANUFACTURE

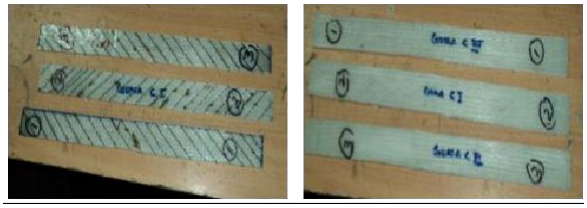
In this process resin and hardener are mixed in the ratio of 10:1 at normal room temperature to get epoxy. The mould should be well cleaned and dry. Release agent is applied and the epoxy mixture is uniformly applied. First mat is laid into the moulded.Apply the resin on mat by brush. Roller is used to swipe the unused epoxy and then second mat is laid on to the first mat. Repeat the process up to 3 layers.

For stitched specimen the stitches are made 4 stitches per sq cm. stitches are made perpendicular to the direction of fiber orientation. Machined specimens are as follows

Tensile test specimen ASTM D 638

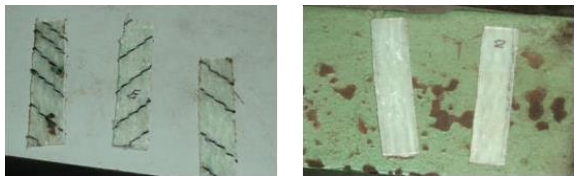
Stitched Un stitched

Compression test ASTM D 790



Stitched Un stitched

Impact test specimen



Stitched Un stitched

4. RESULTS AND DISCUSSION

Specimens are made for tensile test in the standard of ASTM D638 and for compression test ASTM D790 is machined.

Tensile, compression and impact test are conducted and the ultimate tensile strength ,Breaking load and maximum deflection are depicted in the graphs.

TEST RESULT 2				
S.no	Test name	Test description	Stitched specimen	Un stitched specimen
1	Tensile test	Ultimate Breaking Load	25.62kN	22.4kN
		Ultimate Stress	626N/sq mm	583N/sq mm
2	Compression test	Ultimate Breaking Load	0.74kN	0.47kN
3	Impact test without notch	Izod Test (Energy Stored in Joules)	12	10

CONCLUSION

Tensile, Flexural and impact tests were carried out in unstitched and stitched glass-Fibre /Epoxy laminates. A cotton polyester thread was used to stitch prepare layers in fibre direction with stitch density of 4 stitches/sq cm.The specimens were tested at different Test as discussed above. The Strength and breaking Loads and displacement was evaluated. The following conclusions were drawn on the impact response of the unstitched and stitched laminates.Impact force have been evaluated experimentally by drawing a graph between load Vs. deformation for both stitched and unstitched laminates.From the graph it is found that the peak force of unstitched laminate is more than the stitched laminates.Stitching of the laminate will further improve the delamination resistance, Also from the above obtained results, we may conclude stitched laminate is more strengthening than the un-stitched laminates.From the tensile testing we found, the stitched specimen is observed the breaking load is more than the un-stitched specimen. So the stitched specimen breaking strength is more.

Abstract

The growing demand for sustainable and lightweight engineering materials has intensified research into natural fibre reinforced polymer composites. Among natural fibres, flax fibre has gained significant attention due to its favourable mechanical properties, low density, renewability, and biodegradability. However, inherent limitations such as poor fibre–matrix interfacial bonding, moisture sensitivity, and moderate mechanical strength restrict its wider structural application. To overcome these challenges, ceramic fillers—particularly alumina (Al_2O_3)—have been incorporated into flax fibre composites to enhance mechanical, thermal, and tribological performance. This review critically examines the influence of Al_2O_3 fillers, in both micro- and nano-scale forms, on the properties of flax fibre reinforced polymer composites. Emphasis is placed on material selection, fibre surface treatment, processing techniques, dispersion behaviour of Al_2O_3, and their effects on tensile, flexural, impact, and wear properties. Morphological characteristics and interfacial mechanisms governing composite performance are also discussed. A comparative evaluation of reported studies reveals that optimum Al_2O_3 loading significantly improves load transfer efficiency and damage resistance, while excessive filler addition leads to agglomeration and performance degradation. Finally, existing research gaps, challenges, and future research directions for flax–Al_2O_3 hybrid composites are identified, highlighting their potential for sustainable automotive and semi-structural applications.

Keywords: Flax fibre, Alumina (Al_2O_3), Natural fibre composites, Nano composites, Mechanical properties

Introduction

The growing demand for environmentally sustainable materials has led to increased research interest in natural fibre reinforced polymer composites (NFRPCs). Traditional synthetic fibre composites such as glass fibre reinforced polymers (GFRP) and carbon fibre reinforced polymers (CFRP) provide excellent mechanical performance but pose environmental challenges due to their non-biodegradable nature and high energy consumption during manufacturing. In contrast, natural fibre composites offer several advantages including renewability, biodegradability, lower density, reduced environmental impact, and lower production cost [1–4]. Natural fibre reinforced composites typically consist of natural fibre reinforcement embedded in a polymer matrix, sometimes combined with inorganic fillers to enhance mechanical and thermal performance. The basic structure of natural fibre composites and the interaction between fibres, matrix, and fillers are illustrated in Fig. 1. Natural fibres such as flax, hemp, jute, kenaf, sisal, and bamboo have been widely investigated as reinforcement materials in polymer matrices [5–7]. Among these fibres, flax fibre has gained considerable attention due to its relatively high mechanical strength and stiffness compared with other natural fibres. Pickering et al. reported that flax fibres exhibit tensile strengths ranging from 500 to 1500 MPa and a Young's modulus of approximately 50–70 GPa, making them attractive for lightweight engineering applications [2,8].

Flax fibre composites have been successfully applied in automotive interior panels, sporting goods, marine components, and building materials [9–11].

Their low density and good mechanical properties enable the production of lightweight structures that contribute to improved fuel efficiency and reduced carbon emissions in transportation industries. Despite these advantages, natural fibre composites exhibit several limitations. The hydrophilic nature of natural fibres leads to poor compatibility with hydrophobic polymer matrices, resulting in weak fibre–matrix interfacial bonding. Additionally, natural fibre composites often exhibit high moisture absorption, reduced thermal stability, and limited wear resistance [3,12,13].

Figure 1.: Natural fibre composite structure showing flax fibre reinforcement, polymer matrix and alumina fillers

To overcome these limitations, researchers have investigated several strategies including chemical surface treatment, hybrid reinforcement, and incorporation of inorganic fillers or nanoparticles into polymer matrices [14–16].Among various fillers, alumina (Al_2O_3) has received considerable attention due to its high hardness, thermal stability, and wear resistance. The incorporation of alumina fillers into flax fibre reinforced composites has been reported to significantly enhance mechanical strength, thermal stability, and tribological performance [17–19].

2. Natural Fibre Reinforced Polymer Composites

Natural fibre reinforced polymer composites (NFRPCs) have gained significant attention due to their environmental benefits and promising mechanical performance [4,20,21]. These composites are produced by reinforcing polymer matrices with natural fibres obtained from renewable plant sources. Compared with conventional synthetic fibre composites, natural fibre composites offer a more sustainable alternative because they are biodegradable, renewable, and require lower energy during production. Increasing environmental awareness and the demand for sustainable materials have further encouraged the development and use of these composites [4,20,21]. Natural fibres are mainly composed of cellulose, hemicellulose, lignin, and pectin, which influence their mechanical behaviour and interaction with polymer matrices. Among these components, cellulose contributes significantly to the strength and stiffness of the fibres due to its crystalline structure. Natural fibres are typically embedded in polymer matrices such as epoxy, polyester, or polypropylene to produce composite materials with improved mechanical properties [4,20,21]. Natural fibre composites provide several advantages over traditional synthetic composites. They have low density, good specific strength, renewability, biodegradability, and lower cost. These characteristics make them suitable for applications in industries such as automotive, construction, and consumer products. In addition, the use of natural fibres helps reduce environmental impact and supports the development of eco-friendly materials [1,4,20]. However, natural fibre composites also have some limitations. The properties of natural fibres may vary due to differences in plant species and growing conditions. Furthermore, natural fibres are hydrophilic, meaning they

absorb moisture easily, which can weaken the fibre–matrix interface and reduce mechanical performance. Natural fibres also have relatively lower thermal stability compared with synthetic fibres [3,13,21]. To improve the performance of natural fibre composites, researchers have explored several approaches such as chemical surface treatment, hybrid reinforcement, and the addition of nanoparticles or ceramic fillers. These techniques can enhance fibre–matrix bonding and improve mechanical and thermal properties [14,15,22].

3. Flax Fibre Reinforced Polymer Composites

Flax fibres are derived from the *Linum usitatissimum* plant and are widely used in composite materials due to their excellent mechanical properties and environmental benefits [8,9]. Flax fibres possess relatively high cellulose content, which contributes to their stiffness and tensile strength. Several studies have investigated the mechanical behaviour of flax fibre reinforced polymer composites. Woven flax/epoxy composites have demonstrated improved load transfer efficiency and structural stability compared with randomly oriented fibres [23]. Madhu et al. reported that optimized laminate configurations significantly enhanced tensile strength and stiffness in flax fibre reinforced epoxy composites [24]. Similarly, other studies have highlighted that fibre architecture and stacking sequence play a significant role in determining the mechanical performance of flax fibre composites [25]. Furthermore, the morphology and structure of flax fibre bundles strongly influence composite properties. Improved fibre alignment and bundle structure can enhance the tensile properties and stiffness of flax fibre composites [26]. Despite these promising results, flax fibre composites still suffer from several limitations such as poor fibre–matrix bonding and moisture sensitivity, which can negatively affect long-term performance [3,12].

4. Alumina (Al_2O_3) Fillers in Polymer Composites

Ceramic fillers have been widely used to enhance the performance of polymer composites by improving their mechanical, thermal, and tribological properties [27–29]. These fillers are commonly incorporated into polymer matrices to increase stiffness, hardness, and overall durability of composite materials. Among the various ceramic fillers available, alumina (Al_2O_3) has gained considerable attention because of its excellent hardness, high thermal stability, good wear resistance, and chemical inertness. Due to these advantageous characteristics, alumina is frequently used as a reinforcing filler in polymer-based composites for advanced engineering applications.

Alumina particles can be incorporated into polymer matrices in different sizes, including micro-sized and nano-sized particles. Micro-sized alumina particles primarily enhance the stiffness and wear resistance of the composite by acting as rigid reinforcements within the polymer matrix. On the other hand, nano-sized alumina particles provide a significantly larger surface area, which promotes better interaction between the filler particles and the surrounding polymer matrix. This improved interfacial interaction leads to better stress distribution and enhanced reinforcement efficiency within the composite structure [30].

Several studies have reported that the addition of alumina fillers significantly improves the tensile strength, hardness, and wear resistance of polymer composites. The presence of rigid ceramic particles increases the stiffness of the matrix and restricts deformation under applied loads, thereby improving the load-bearing capacity of the composite material [31]. Furthermore, ceramic nanofillers can enhance the stress transfer mechanism between the polymer matrix and reinforcing fibres, leading to improved mechanical

behaviour in fibre reinforced polymer composites [17,18].

In addition to mechanical improvements, the incorporation of alumina fillers also enhances the thermal conductivity and dimensional stability of polymer composites. These properties are particularly important in applications where materials are exposed to elevated temperatures or thermal fluctuations. As a result, alumina-filled polymer composites are increasingly being used in automotive, aerospace, and structural engineering components, where improved mechanical strength, wear resistance, and thermal stability are required [29,30].

5. Mechanical Properties of Flax/Al_2O_3 Composites

The mechanical properties of flax fibre reinforced polymer composites can be significantly improved through the incorporation of ceramic fillers such as alumina. The addition of alumina particles increases the stiffness of the polymer matrix and promotes more effective stress transfer between the reinforcing fibres and the surrounding matrix material [18,19]. This improved stress transfer mechanism allows the composite to withstand higher loads and enhances its overall structural performance. As a result, filler-reinforced composites often exhibit improved tensile strength, flexural strength, and impact resistance compared with composites without fillers.

Several experimental studies have demonstrated the beneficial effects of alumina fillers on the mechanical behaviour of flax fibre composites. Sathish et al. investigated the mechanical performance of flax fibre reinforced epoxy composites containing silicon carbide (SiC) and alumina (Al_2O_3) fillers and reported significant improvements in tensile strength, flexural strength, and impact resistance when compared with unfilled composites [19]. These improvements were mainly attributed to the increased stiffness of the matrix and improved fibre–matrix bonding caused by the presence of ceramic particles.

Similarly, other studies have reported that the addition of alumina fillers to flax fibre composites results in noticeable improvements in tensile strength and impact resistance due to enhanced interaction between the fibres and the polymer matrix [32]. The rigid ceramic particles act as reinforcement within the matrix and restrict deformation under applied loads, thereby increasing the load-bearing capacity of the composite material.

In addition to micro-sized fillers, the use of nano-sized alumina particles has also been shown to significantly enhance the mechanical properties of flax fibre composites. Nano-Al_2O_3 particles provide a larger surface area for interaction with the polymer matrix, which improves interfacial bonding and allows for better stress distribution throughout the composite structure [33]. This results in improved tensile and flexural properties.

However, the effectiveness of alumina fillers strongly depends on the uniform dispersion of particles within the matrix. Poor dispersion or nanoparticle agglomeration can create stress concentration regions, which may lead to premature failure and reduced mechanical performance of the composite material [27,30].

6. Thermal Behaviour of Flax Fibre Composites with Alumina Fillers

Thermal stability is an important parameter for polymer composites used in various engineering applications, particularly in industries where materials are exposed to elevated temperatures or thermal fluctuations. Natural fibre reinforced composites generally exhibit lower thermal stability compared with synthetic fibre composites because natural fibres begin to degrade at relatively lower temperatures [13,21]. This limitation restricts the use of natural fibre composites in high-temperature environments and certain structural applications.

The thermal degradation of natural fibres mainly occurs due to the decomposition of their primary constituents, including hemicellulose, cellulose, and lignin. Hemicellulose typically degrades at temperatures between 200–300 °C, while cellulose decomposes around 300–350 °C, and lignin degrades gradually over a wider temperature range. As a result, natural fibre composites may experience thermal deterioration when exposed to high temperatures for prolonged periods. Improving the thermal stability of these composites is therefore essential for expanding their engineering applications [13,21].

One effective approach to enhance the thermal stability of natural fibre composites is the incorporation of ceramic fillers such as alumina (Al_2O_3). Alumina particles possess excellent thermal resistance and high melting temperatures, which allow them to act as thermal barriers within the composite structure. The addition of alumina nanoparticles can increase the thermal degradation temperature of the composite and improve its resistance to heat and thermal aging [34]. These particles also help reduce thermal expansion and improve dimensional stability under elevated temperatures.

Thermal analysis studies conducted on flax fibre reinforced composites have shown that the incorporation of reinforcing fillers leads to improved thermal stability and enhanced resistance to thermal degradation [35]. This improvement is mainly attributed to the strong interaction between the filler particles and the polymer matrix, which restricts molecular mobility and slows down the degradation process.

To evaluate the thermal behaviour of such composites, researchers commonly use thermal analysis techniques such as thermogravimetric analysis (TGA) and differential scanning calorimetry (DSC). These techniques provide valuable information about thermal degradation temperature, heat flow behaviour, and overall thermal stability of the composite materials [36].

7. Tribological Properties of Flax/Al_2O_3 Composites

Tribological properties, including wear resistance and friction behaviour, play an important role in determining the suitability of composite materials for many engineering applications such as automotive components, bearings, gears, and sliding mechanical parts [37]. Materials used in such applications are frequently subjected to repeated contact, friction, and surface wear. Therefore, improving the tribological performance of polymer composites is essential to ensure longer service life and reliable performance.

Natural fibre reinforced polymer composites often exhibit limited wear resistance because the polymer matrix used in these materials is relatively soft compared with ceramic or metallic materials. During sliding or abrasive contact, the polymer matrix may undergo surface deformation, material removal, or microcracking, which leads to increased wear rates. This limitation restricts the use of natural fibre composites in applications where high frictional forces and severe wear conditions are present.

One effective method to enhance the tribological behaviour of these composites is the incorporation of ceramic fillers such as alumina (Al_2O_3). Alumina particles are well known for their high hardness, excellent abrasion resistance, and strong thermal stability. When dispersed within the polymer matrix, these particles act as hard reinforcement phases that improve the surface hardness of the composite and reduce material removal during sliding contact. As a result, the presence of alumina fillers significantly improves the wear resistance and surface durability of fibre reinforced polymer composites [31,37].

Several experimental studies have reported that ceramic-filled natural fibre composites exhibit a significant reduction

in wear rate compared with unfilled composites. The hard ceramic particles help protect the matrix from severe abrasion and distribute the applied load more effectively across the composite surface [38]. In addition to single filler reinforcement, hybrid reinforcement strategies have also been explored. For example, the use of nanoparticles such as zinc oxide (ZnO) and alumina (Al_2O_3) together has shown promising improvements in tribological performance by reducing friction and enhancing wear resistance [39]. These hybrid filler systems can provide better reinforcement and improved surface protection, making them suitable for demanding engineering applications.

8. Water Absorption and Environmental Durability

Moisture absorption is one of the major challenges associated with natural fibre reinforced polymer composites because natural fibres are inherently hydrophilic in nature [3,12]. Natural fibres contain hydroxyl groups in their cellulose structure, which readily attract and absorb water molecules from the surrounding environment. When these fibres are incorporated into polymer matrices, the composite material may absorb moisture when exposed to humid conditions, water, or outdoor environments. This moisture absorption can significantly influence the physical and mechanical properties of the composite material.

Moisture diffusion into the composite structure leads to several detrimental effects. As water molecules penetrate the material, the natural fibres tend to swell, which creates internal stresses within the composite structure. This swelling can cause the formation of micro-cracks and interfacial gaps between the fibre and the polymer matrix. As a result, the bonding between the fibres and the matrix becomes weaker, reducing the efficiency of stress transfer within the composite. Consequently, the overall mechanical performance, stiffness, and strength of the composite material decrease over time [21].

Hydrothermal ageing studies have further demonstrated the negative impact of moisture exposure on natural fibre composites. When flax fibre reinforced composites are exposed to moisture for extended periods, their tensile strength, flexural strength, and stiffness can significantly decrease due to fibre degradation and weakening of the fibre–matrix interface [40]. Long-term exposure to moisture may also lead to matrix plasticization and dimensional instability, which can further reduce the durability of the composite.

To mitigate these issues, researchers have explored several approaches to improve the environmental durability of natural fibre composites. One effective strategy is the incorporation of inorganic fillers or nanoparticles into the polymer matrix. The addition of fillers can reduce moisture diffusion pathways by minimizing micro-voids and improving matrix densification. This results in better barrier properties and improved resistance to moisture penetration. Consequently, filler-reinforced composites exhibit enhanced environmental stability and durability, making them more suitable for structural and outdoor applications.

9. Research Gaps and Future Directions

Although significant research has been carried out on natural fibre reinforced polymer composites and ceramic filler reinforced polymers, relatively few studies have specifically focused on flax fibre reinforced composites modified with alumina nanoparticles. While existing studies indicate that alumina fillers can improve mechanical strength, thermal stability, and wear resistance, further investigation is required to fully understand and optimize their performance in flax fibre based composites.

Future research should focus on several important aspects. First,

optimization of alumina filler content is necessary to achieve the best balance between mechanical performance and material processability. Excessive filler loading may lead to particle agglomeration and reduced composite performance. Second, surface treatment of flax fibres can improve fibre–matrix adhesion and reduce moisture absorption. Third, hybrid reinforcement strategies, combining alumina with other nanoparticles or fibres, may further enhance composite properties. Additionally, long-term durability studies under environmental conditions are required. Finally, the development of biodegradable polymer matrices will support the production of fully sustainable composite materials.

10. Conclusion

Flax fibre reinforced polymer composites (FFRPCs) have emerged as a promising class of sustainable materials for lightweight engineering applications due to their environmentally friendly characteristics and favourable mechanical properties. Flax fibres are derived from renewable plant sources and possess relatively high tensile strength and stiffness compared with many other natural fibres. When combined with polymer matrices such as epoxy, polyester, or biodegradable polymers, flax fibres can produce composite materials with good strength-to-weight ratios, making them suitable for applications in automotive components, structural panels, sporting goods, and construction materials. The use of flax fibre composites also contributes to reduced environmental impact by lowering energy consumption during manufacturing and supporting the use of biodegradable or recyclable materials. Despite these advantages, flax fibre composites still face several performance limitations. One of the main challenges is moisture absorption, which occurs because natural fibres are hydrophilic in nature. When exposed to humid environments, flax fibres tend to absorb moisture, leading to swelling, microcrack formation, and weakening of the fibre–matrix interface. This can result in a reduction in mechanical strength and long-term durability of the composite material. In addition, natural fibre composites generally exhibit lower thermal stability compared with synthetic fibre composites, which restricts their application in high-temperature environments. Another limitation is their relatively poor tribological performance, including higher wear rates and lower surface hardness. To address these challenges, researchers have investigated the incorporation of ceramic fillers such as alumina (Al_2O_3) into flax fibre reinforced composites. Alumina particles possess high hardness, good thermal stability, and excellent wear resistance, making them effective reinforcement materials for polymer matrices. The addition of alumina fillers can significantly improve the mechanical strength, stiffness, and wear resistance of flax fibre composites. Furthermore, alumina particles enhance the fibre–matrix interfacial bonding and increase resistance to thermal degradation, thereby improving overall composite performance. Although these improvements have been reported, further research is still required to optimize filler dispersion, interfacial adhesion, and long-term environmental durability to fully exploit the potential of flax fibre reinforced composites for advanced engineering applications.

Effectiveness of Clay-Based Prosthetic Implants for Amputated Metatarsus: Implications for Gait Restoration and Biocompatibility – A Review

B Bradley Bright

Assistant professor

Department of Mechanical Engineering

Panimalar Engineering College, Chennai – 600123, Tamilnadu, India.

Abstract

Metatarsal amputation significantly alters the biomechanical function of the foot, resulting in impaired gait, instability, and abnormal pressure distribution. Prosthetic implants are commonly used to restore foot function; however, traditional materials such as metals and polymers may present limitations including poor biological integration and inflammatory responses. Recent advances in biomaterials have highlighted the potential of clay-based nanocomposites as promising candidates for orthopaedic and prosthetic applications. Clay minerals such as montmorillonite, halloysite nanotubes, and kaolinite possess unique characteristics including high surface area, ion-exchange capability, mechanical reinforcement properties, and excellent biocompatibility. These properties make them suitable for bone regeneration and prosthetic scaffold development. This review examines the effectiveness of clay-based prosthetic implants in reconstructing amputated metatarsal bones, focusing on their role in restoring gait mechanics and maintaining biocompatibility. Current studies indicate that clay-reinforced biomaterials enhance osteogenesis, improve mechanical strength, and promote cellular proliferation without significant cytotoxicity. These characteristics suggest that clay-based prosthetic materials may contribute to improved implant integration and functional recovery in patients with metatarsal amputation. Further research and clinical studies are necessary to validate long-term outcomes and optimize implant design.

Keywords: Clay biomaterials, prosthetic implants, metatarsal amputation, gait restoration, biocompatibility, bone tissue engineering

Introduction

The human foot plays a crucial role in maintaining balance, mobility, and efficient locomotion. Among its structural components, the metatarsal bones serve as essential load-bearing elements that contribute to weight distribution and propulsion during walking and running [1]. The metatarsus consists of five long bones positioned between the tarsal bones and the phalanges, forming an integral part of the forefoot structure. These bones help maintain the longitudinal and transverse arches of the foot while enabling effective transfer of forces from the hindfoot to the toes during the push-off phase of gait [2].

Metatarsal amputation may occur due to traumatic injuries, diabetic foot complications, infections, vascular diseases, or malignant tumors [3]. Such amputations often lead to significant biomechanical alterations in the foot, including reduced forefoot leverage, altered pressure distribution, and decreased push-off efficiency during walking [4]. As a result, patients frequently experience impaired gait patterns, reduced walking speed, instability, and increased metabolic energy expenditure during locomotion [5].

The metatarsal bones play a critical role in maintaining the structural integrity and functional biomechanics of the human foot [20]. These bones support body weight, maintain foot arches, and facilitate propulsion during walking and running [21]. Damage or amputation of the metatarsal bones may occur due to trauma, diabetic complications, infections, or tumors [22]. Such conditions lead to significant biomechanical alterations in the foot, resulting in impaired gait patterns, instability, and increased energy expenditure during locomotion [23].

Prosthetic reconstruction is widely used to restore the anatomical structure and functional capability of the foot following amputation [24]. Conventional prosthetic implants are typically fabricated from materials such as titanium alloys, stainless steel, ceramics, and polymer composites [25]. Although these materials provide adequate mechanical strength, they may also cause complications including stress shielding, poor osseointegration, and inflammatory reactions [26].

Recent developments in biomaterials research have introduced clay-based nanocomposites as promising alternatives for orthopedic implants [27]. Clay minerals possess unique physicochemical properties such as high surface area, layered structure, adsorption capacity, and ion-exchange capability [28]. These characteristics enable clay materials to interact effectively with biological tissues and promote cellular growth and tissue regeneration [29].

This review aims to evaluate the effectiveness of clay-based prosthetic implants for amputated metatarsus, focusing on their role in restoring gait mechanics and maintaining biocompatibility.

2. Literature Survey

2.1. Diabetic Foot Ulcers and Offloading Strategies

Diabetic foot ulcers (DFUs) are among the most serious complications of diabetes mellitus and often lead to infection, hospitalization, and lower-limb amputation. Elevated plantar pressure caused by peripheral neuropathy and structural foot deformities plays a critical role in ulcer development and

delayed healing. Offloading interventions such as therapeutic footwear, orthoses, and pressure-redistributing devices are therefore widely recommended for both prevention and treatment of DFUs [1,32,54]. Peripheral neuropathy also alters gait biomechanics, increasing the risk of ulceration. Patients with diabetic neuropathy demonstrate reduced ankle mobility, altered walking patterns, and increased forefoot loading compared with healthy individuals [3]. Such biomechanical abnormalities highlight the importance of pressure-relieving devices and improved prosthetic solutions to prevent further tissue damage.

2.2. Biomechanical Effects of Partial Foot Amputation

Although these procedures preserve limb length, they significantly affect gait mechanics and functional mobility. Studies have shown that loss of the forefoot reduces push-off power during walking and alters the natural biomechanics of the foot [2].

Patients with partial foot amputations often demonstrate reduced walking speed, shorter stride length, and abnormal distribution of ground reaction forces during gait [22,53]. In particular, transmetatarsal amputations alter center-of-pressure progression and compromise balance and propulsion during walking [52]. These biomechanical changes may also lead to secondary musculoskeletal complications and overuse injuries in the remaining limb due to altered load distribution [51].

2.3. Mechanical Function of the Human Foot

The human foot functions as a complex biomechanical structure designed to support body weight and facilitate locomotion. The plantar aponeurosis and longitudinal arch play a crucial role in maintaining foot stability and efficient energy transfer during gait. The "windlass mechanism," which involves tightening of the plantar fascia during toe dorsiflexion, helps stabilize the arch during push-off [19].

The toes also contribute significantly to propulsion and balance during walking and running. The absence or dysfunction of these structures, such as after partial foot amputation, can reduce mechanical efficiency and impair gait performance [20]. Consequently, prosthetic or orthotic interventions are required to restore normal biomechanical function.

2.4. Biomaterials Used in Orthopedic and Prosthetic Applications

The success of orthopedic implants and prosthetic devices depends largely on the properties of the materials used in their construction. Titanium and its alloys are widely used in biomedical implants due to their excellent biocompatibility, corrosion resistance, and high strength-to-weight ratio [4].

Titanium alloys also possess favorable mechanical characteristics such as high fatigue strength and good resistance to cyclic loading, making them suitable for load-bearing orthopedic applications [5]. In addition, titanium implants demonstrate strong osseointegration with surrounding bone tissue, improving long-term implant stability [24,49].

However, conventional metallic implants may cause stress shielding, a phenomenon in which the implant carries a larger portion of the mechanical load than the surrounding bone. This may result in bone resorption and reduced implant fixation over time [6,34,57]. Therefore, recent research has focused on developing advanced biomaterials and composite structures that better mimic the mechanical properties of natural bone.

2.5. Polymer–Clay Nanocomposites for Biomedical Applications

Polymer–clay nanocomposites have attracted considerable attention in biomedical engineering due to their enhanced mechanical, thermal, and barrier properties. Incorporation of layered silicate clays into polymer matrices can significantly improve stiffness, strength, and structural stability of the composite materials [8,9].

The nanoscale dispersion of clay particles within polymer matrices provides improved mechanical reinforcement while maintaining lightweight characteristics, making these materials suitable for biomedical devices and prosthetic applications [36]. Clay minerals are also widely used in pharmaceutical and cosmetic industries because of their adsorption properties and biocompatibility [10].

2.6. Nanoclay-Based Biomaterials in Regenerative Medicine

Recent developments in nanotechnology have led to the emergence of nanoclay-based biomaterials for regenerative medicine. Two-dimensional nanosilicates and halloysite nanotubes have been extensively studied for their ability to enhance the mechanical properties and biological performance of biomaterials [7,30,42].

Nanoclay particles can reinforce polymer scaffolds and stimulate cellular activities such as proliferation and differentiation, making them promising materials for tissue engineering applications [17,18,29]. Clay-based scaffolds have also been shown to support bone regeneration by promoting osteogenic differentiation of stem cells [14,31,44].

Furthermore, nanoclay materials can function as drug-delivery systems due to their high surface area and layered structure, which enable encapsulation and sustained release of therapeutic agents [13,41]. Studies have also demonstrated that nanoclay-reinforced scaffolds can enhance angiogenesis and vascularization, which are essential for successful tissue regeneration [16,40].

2.7. Research Gap

Although considerable progress has been made in the development of prosthetic devices, orthopedic biomaterials, and nanoclay-based scaffolds, challenges still remain in improving functional outcomes for patients with diabetic foot complications and partial foot amputations. Traditional implant materials may suffer from stress shielding and limited biological activity, while current offloading devices may not fully restore natural gait mechanics. Nanoclay-based biomaterials and polymer nanocomposites provide promising opportunities for the development of advanced prosthetic and orthopedic solutions with improved mechanical strength, antibacterial properties, and regenerative capabilities. However, further research is required to optimize these materials for clinical translation and long-term performance.

3. Anatomy and Biomechanical Role of the Metatarsus

The metatarsus forms the structural and functional core of the forefoot and plays a crucial role in weight transmission, balance, and propulsion during locomotion. Anatomically, the metatarsus consists of five elongated bones located between the tarsal bones of the midfoot and the phalanges of the toes. Each metatarsal is composed of a proximal base, a cylindrical shaft, and a distal head that articulates with the proximal phalanx through the metatarsophalangeal (MTP) joint. This anatomical arrangement allows the metatarsals to function as load-bearing struts that distribute body weight

from the hindfoot and midfoot toward the toes during movement.

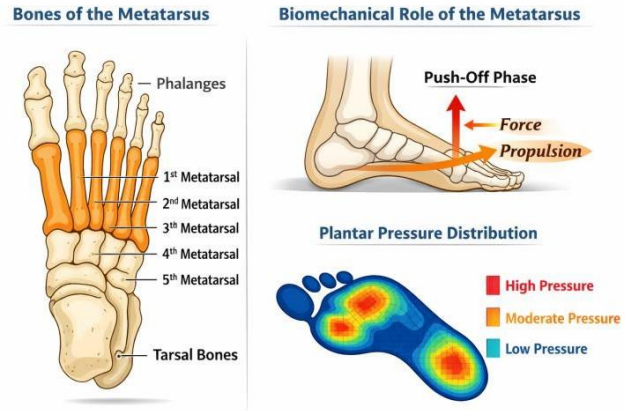

Figure 1 Metatarsal Anatomy and Biomechanical Function Illustrating Push-Off Mechanics and Plantar Pressure Distribution.

As illustrated in **Figure 1,** the five metatarsal bones are arranged from the medial to the lateral side and are labelled as the first through fifth metatarsals. The first metatarsal is typically the shortest but structurally the strongest, reflecting its significant role in weight bearing during the propulsion phase of gait. The second metatarsal is generally the longest and occupies a relatively fixed position within the tarsometatarsal joint complex, providing stability to the forefoot. The third, fourth, and fifth metatarsals gradually decrease in size and possess greater mobility, allowing the foot to adapt to irregular ground surfaces and maintain balance.

The metatarsal bones also contribute to the maintenance of the **longitudinal and transverse arches of the foot**, which are critical for mechanical efficiency and shock absorption. The medial longitudinal arch, primarily supported by the first and second metatarsals, functions as an elastic structure that absorbs impact forces during heel strike and stores mechanical energy that is later released during push-off. Meanwhile, the transverse arch formed by the metatarsal bases and heads distributes loads across the forefoot and prevents excessive localized pressure. The structural integrity of these arches is maintained through coordinated interactions among ligaments, intrinsic foot muscles, and the plantar fascia.

From a biomechanical standpoint, the metatarsus plays a pivotal role during the **push-off phase of gait**, as depicted in the diagram. During walking, body weight is initially transferred from the heel toward the midfoot and subsequently toward the forefoot. As the stance phase progresses, increasing load is applied to the metatarsal heads. During the terminal stance stage, dorsiflexion of the toes tightens the plantar fascia through the windlass mechanism, first described by John H. Hicks. This mechanism elevates and stabilizes the medial longitudinal arch, converting the foot into a rigid lever that enhances propulsion and forward movement [19]. The diagram highlights how the metatarsal region acts as the pivot point where muscular force is translated into forward propulsion.

Another important biomechanical feature shown in the figure is the **distribution of plantar pressure across the forefoot**. Plantar pressure mapping reveals that the highest pressures typically occur beneath the first and second metatarsal heads, as these structures bear a substantial portion of body weight during the push-off phase. Moderate pressure is observed across the central metatarsals, while relatively lower pressure occurs toward the lateral forefoot. This pressure distribution pattern ensures that mechanical loads are shared efficiently across the forefoot, minimizing the risk of localized stress concentrations.

However, alterations in this pressure distribution can occur due to pathological conditions or structural abnormalities. In individuals with diabetes mellitus, peripheral neuropathy and reduced protective sensation often lead to abnormal plantar loading patterns. Excessive pressure beneath the metatarsal heads is widely recognized as a primary biomechanical factor contributing to the development of diabetic foot ulcers [1,21]. The pressure map illustrated in the figure demonstrates how localized high-pressure zones may develop beneath specific metatarsal heads, which increases the risk of tissue breakdown and ulceration if not properly managed.

During standing and dynamic movements, the metatarsal heads form an essential part of the forefoot support platform, providing a broad base that stabilizes the body's center of mass. Sensory receptors located in the plantar surface of the forefoot detect pressure and ground contact, enabling rapid neuromuscular adjustments that maintain equilibrium and coordination.

Furthermore, disruption of the metatarsal structure—such as through trauma, deformity, or partial foot amputation—can significantly impair gait biomechanics. Loss of metatarsal segments alters the natural load distribution and reduces the efficiency of the push-off mechanism. Consequently, affected individuals often demonstrate decreased walking speed, altered center-of-pressure progression, and reduced propulsive power during locomotion [22,53]. These biomechanical alterations may lead to compensatory gait patterns and increased mechanical stress on adjacent joints and the contralateral limb.

In summary, the metatarsus serves as a fundamental biomechanical component of the human foot, integrating structural support with dynamic functionality. Through its anatomical configuration and interaction with surrounding soft tissues, it enables efficient weight distribution, shock absorption, and propulsion during locomotion. The diagram presented in Figure X visually illustrates these roles by highlighting the anatomical arrangement of the metatarsal bones, their contribution to propulsion during the push-off phase, and the characteristic pattern of plantar pressure distribution across the forefoot. Understanding these biomechanical principles is essential for the development of effective orthopaedic treatments, prosthetic devices, and therapeutic strategies aimed at restoring normal foot function and preventing complications such as plantar ulceration.

4. Gait Alterations Following Metatarsal Amputation

Metatarsal amputation, particularly partial foot amputations involving the removal of one or more metatarsal bones, leads to significant biomechanical changes that affect gait efficiency, balance, and propulsion. The metatarsus plays a vital role in transferring body weight during the stance phase of gait and in generating forward propulsion during push-off. During normal gait, body weight is transferred progressively from the heel to the midfoot and finally to the

forefoot, where the metatarsal heads function as pivot points for propulsion. This process allows the foot to operate as a rigid lever during the terminal stance phase. However, following metatarsal amputation, this lever mechanism is disrupted, leading to diminished push-off power and reduced walking efficiency. Clinical gait analyses have shown that individuals with partial foot amputations often demonstrate slower walking speeds, shorter stride lengths, and increased time spent in the double-support phase of the gait cycle [22,53].

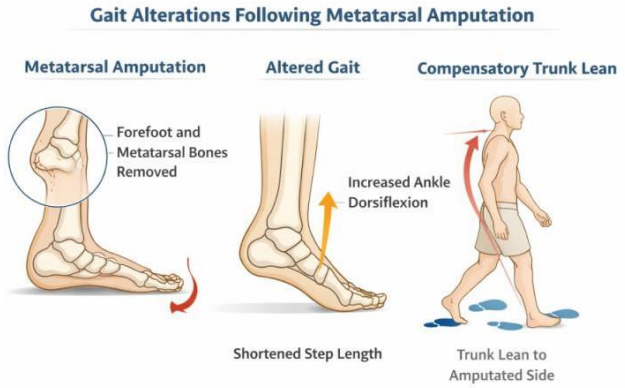

Figure 2 Altered Gait Pattern and Postural Compensation After Metatarsal Amputation

Figure 2 illustrates the primary biomechanical consequences of metatarsal amputation and the compensatory adaptations observed during walking. The left panel of the diagram shows the anatomical condition following amputation, where the forefoot and metatarsal bones have been removed. This loss of structural support reduces the length of the foot lever arm and alters the normal rollover mechanism that occurs during gait. As a result, the ability of the forefoot to transmit propulsive forces is significantly diminished.

The central portion of the diagram demonstrates the **altered gait mechanics** that arise following amputation. One key biomechanical change is **increased ankle dorsiflexion during stance**, which occurs because the shortened forefoot cannot effectively resist forward tibial progression. Without the stabilizing influence of the metatarsal heads, the ankle joint experiences greater dorsiflexion as the body moves over the residual limb. This altered ankle motion contributes to instability and reduces the efficiency of the push-off phase.

Another prominent feature illustrated in the diagram is the **shortened step length**, which is commonly observed in individuals with partial foot amputations. Because the propulsive capacity of the affected limb is reduced, patients often limit the forward advancement of the contralateral limb. This adaptation reduces the mechanical demands on the amputated foot but simultaneously decreases overall walking speed and gait symmetry. Reduced step length is therefore a protective but inefficient compensatory strategy that helps maintain balance and minimize discomfort.

The right side of the diagram highlights an additional compensatory mechanism known as **trunk lean toward the amputated side**. Patients frequently shift their upper body toward the affected limb during the stance phase to reposition the body's center of mass closer to the supporting foot. This strategy helps reduce the mechanical moment acting at the ankle and knee joints and improves stability when weight is borne on the shortened limb. However, persistent trunk lean may lead to abnormal loading of the spine and hip joints over time, potentially contributing to musculoskeletal discomfort or secondary degenerative changes.

Beyond the alterations illustrated in the figure, metatarsal amputation also affects plantar pressure distribution across the residual foot. Under normal conditions, the metatarsal heads distribute loads evenly across the forefoot during push-off. Following amputation, the pressure pattern shifts proximally toward the midfoot or laterally toward the remaining structures. This redistribution often results in localized areas of high pressure that increase the risk of skin breakdown and ulcer formation, particularly in patients with diabetes mellitus and peripheral neuropathy [1,21].

The absence of metatarsal support further compromises the structural stability of the foot arches. The medial longitudinal arch depends partly on the integrity of the metatarsals and the tension generated by the plantar fascia. Loss of these structural elements may reduce the foot's ability to store and release elastic energy during gait, leading to increased metabolic energy expenditure during walking.

Compensatory biomechanical adjustments following metatarsal amputation may also extend to proximal joints. Because propulsion from the forefoot is diminished, individuals often rely more heavily on hip and knee musculature to advance the limb during walking. This redistribution of mechanical effort can increase joint loading and contribute to secondary musculoskeletal complications over time. Epidemiological studies have reported a high prevalence of overuse injuries and joint pain in individuals with lower-limb amputations due to these altered loading patterns [51].

To mitigate these gait abnormalities, various prosthetic and orthotic interventions are commonly employed. Devices such as rocker-bottom shoes, custom orthoses, and partial foot prostheses aim to restore a more natural rollover pattern during the stance phase and compensate for the loss of forefoot leverage. These assistive devices help redistribute plantar pressure, improve gait symmetry, and enhance walking efficiency [2].

In summary, metatarsal amputation produces substantial alterations in gait biomechanics due to the loss of forefoot structural support and propulsive capability. As illustrated in Figure X, these changes include increased ankle dorsiflexion, shortened step length, and compensatory trunk lean toward the amputated side. Understanding these biomechanical adaptations is essential for the development of effective prosthetic solutions and rehabilitation strategies aimed at restoring mobility, improving gait efficiency, and preventing secondary complications in individuals with partial foot amputations.

5. Clay-Based Biomaterials in Prosthetic Implants

Clay minerals such as **kaolinite, montmorillonite, bentonite, and halloysite nanotubes** have gained significant attention in biomedical engineering due to their unique structural properties [42].

Clay nanoparticles are commonly incorporated into polymer or ceramic matrices to enhance the mechanical and biological properties of prosthetic implants [43].

Clay-derived biomaterials encompass a diverse group of naturally occurring and engineered silicate minerals that

possess unique structural, chemical, and biological properties suitable for biomedical applications. Their layered or nanotubular architectures provide high surface area, ion-exchange capacity, and mechanical reinforcement potential, making them valuable components in advanced prosthetic and orthopedic biomaterials. These materials can support cellular interactions, enable controlled therapeutic delivery, and enhance the mechanical stability of composite implants.

Table 1 Major Clay-Based Biomaterials and Their Properties, Biomedical Functions, and Potential Applications in Prosthetic Implants.

Clay Biomaterial	Chemical Composition / Structure	Key Properties	Biomedical Functions	Potential Application in Prosthetic Implants
Kaolinite	$Al_2Si_2O_5(OH)_4$ layered silicate mineral	High biocompatibility, low toxicity, moderate mechanical stability	Supports cell adhesion and proliferation; promotes tissue compatibility	Surface coating or filler material in prosthetic implants to improve tissue integration
Montmorillonite	Smectite clay with expandable layered structure containing silica and alumina	High surface area, strong ion-exchange capacity, antimicrobial potential	Drug delivery carrier; enhances antibacterial activity	Incorporation in composite prosthetic materials for infection control and improved implant longevity
Bentonite	Aluminum phyllosilicate primarily composed of montmorillonite	High swelling capacity, high porosity, good adsorption properties	Absorption of toxins and microbial agents; enhanced tissue interaction	Porous scaffold component in prosthetic implants for improved osseointegration
Halloysite Nanoclay	Aluminosilicate nanotubular structure	High mechanical reinforcement capability, nano-tubular morphology	Controlled drug release; improved mechanical strength in composites	Reinforcement material in polymer-clay prosthetic composites
Clay-Ceramic Composites	Hybrid materials combining clay minerals with bio-ceramics (e.g., hydroxyapatite)	Enhanced mechanical strength, improved porosity, high bioactivity	Promotes bone regeneration and integration with surrounding tissues	Structural component for prosthetic implants requiring both strength and bioactivity

6. Biocompatibility of Clay-Based Prosthetic Materials

Biocompatibility is a critical factor in the development of implantable biomaterials, as the material must interact with biological tissues without causing toxicity, inflammation, or adverse immune responses. Clay-based biomaterials have attracted significant attention in recent years due to their **natural origin, chemical stability, and favorable biological interactions**. These properties make them promising candidates for applications in orthopedic and prosthetic implants, including potential use in metatarsal reconstruction

Biocompatibility is a crucial requirement for implantable biomaterials [44]. Clay minerals exhibit low cytotoxicity and good compatibility with mammalian cells [45].

Studies have shown that nanoclay-based scaffolds promote cell adhesion, proliferation, and osteogenic differentiation [46]. Additionally, certain clay minerals exhibit antimicrobial properties against pathogenic bacteria such as *Staphylococcus aureus* and *Escherichia coli* [47].

Overall, existing studies suggest that clay-based biomaterials demonstrate **promising biocompatibility, antimicrobial properties, and potential for tissue integration**, making them attractive candidates for future prosthetic implant designs. However, further experimental and clinical studies are required to evaluate their long-term safety, mechanical durability, and effectiveness in load-bearing prosthetic applications.

Several studies have demonstrated that nanosilicate particles can influence cellular signaling pathways and stimulate osteogenic differentiation in stem cells, thereby promoting bone regeneration and tissue repair [7,39].

These characteristics make clay-based biomaterials attractive candidates for prosthetic implants.

7. Mechanical Properties of Clay-Reinforced Prosthetic Materials

The mechanical performance of prosthetic implants is a critical factor in their clinical success, particularly in load-bearing anatomical regions such as the metatarsus. Materials used in prosthetic reconstruction must possess adequate **strength, stiffness, durability, and fatigue resistance** to

withstand repetitive mechanical stresses generated during walking and other daily activities.

Clay nanoparticles significantly enhance the mechanical properties of composite biomaterials [48]. When incorporated into polymer matrices, nanoclay particles improve tensile strength, compressive strength, and elastic modulus [49].

Additionally, clay reinforcement increases fracture resistance and fatigue durability of prosthetic materials [50]. These improvements are essential for implants that must withstand repetitive mechanical loading during walking.

However, the mechanical performance of clay-based composites depends strongly on factors such as **particle dispersion, clay concentration, and the compatibility between the clay surface and the host matrix**. Poor dispersion may lead to particle agglomeration, which can reduce mechanical strength and create structural weaknesses. To address this limitation, surface modification techniques and hybrid composite systems are often employed to improve the interaction between clay particles and the base material.

Overall, clay-reinforced prosthetic materials demonstrate promising mechanical characteristics, including improved stiffness, strength, and fatigue resistance, while maintaining relatively low density. These properties suggest that clay-based composites could play a significant role in the development of **next-generation prosthetic implants**, particularly when combined with biocompatible polymers or bio-ceramics designed for orthopedic applications. Nevertheless, further experimental and clinical studies are necessary to evaluate their long-term mechanical stability under physiological loading conditions, especially for applications involving load-bearing structures such as the metatarsal bones

8. Role of Clay-Based Implants in Gait Restoration

Metatarsal amputation significantly disrupts the structural integrity and biomechanical function of the forefoot, leading to altered gait patterns, reduced propulsion, and abnormal plantar pressure distribution. Because the metatarsus plays a critical role in load transmission and push-off during walking, its loss often results in impaired locomotion and compensatory postural adjustments. In recent years, **clay-based biomaterials and nanoclay-reinforced implants** have emerged as promising candidates for restoring biomechanical function in patients with partial foot amputations. Clay-based biomaterials, particularly those incorporating nanosilicates or halloysite nanotubes, exhibit excellent reinforcement capabilities when integrated into polymer matrices. These nanostructured materials enhance mechanical strength, stiffness, and durability while maintaining lightweight characteristics, which are essential for load-bearing biomedical implants. In addition to their mechanical advantages, nanoclay materials demonstrate high surface area, bioactivity, and the ability to support cellular interactions, making them promising for tissue integration and regenerative applications [7,17,29].

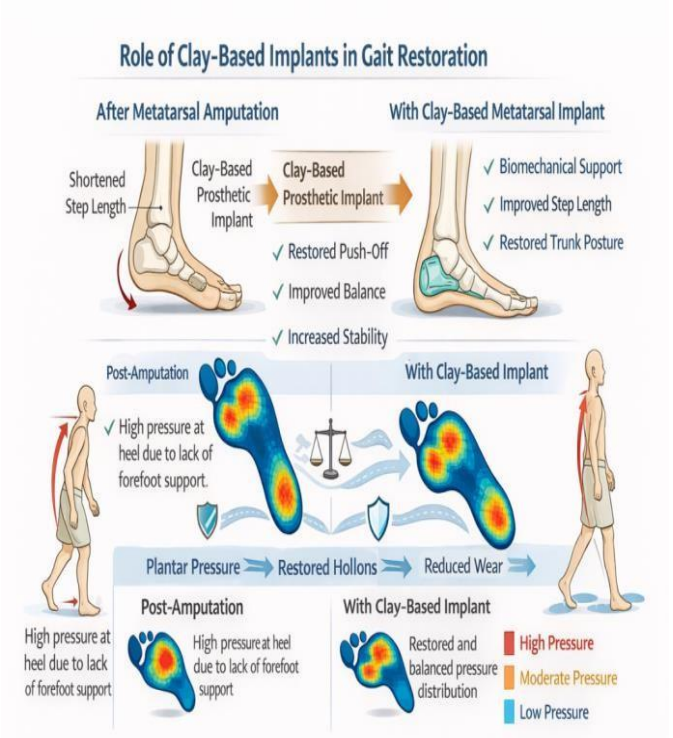

Figure 3 Comparision of Gait Distribution with and Without Implant

The conceptual framework for the use of clay-based implants in restoring gait function is illustrated in **Figure 3**. The left portion of the diagram represents the biomechanical condition following metatarsal amputation. In this state, the forefoot lever arm is shortened due to the absence of metatarsal structures, resulting in **reduced step length and diminished push-off capability** during walking. The loss of forefoot support also alters the rollover mechanism of the foot, forcing the body to rely more heavily on the heel and midfoot during the stance phase.

As shown in the figure, the introduction of a **clay-based prosthetic or structural implant** can help restore some of the lost biomechanical functionality. By replacing or supporting the missing metatarsal structures, the implant effectively recreates the forefoot lever mechanism required for efficient propulsion. This structural restoration enables the foot to generate improved push-off forces during the terminal stance phase of gait. Consequently, patients may experience **improved step length, enhanced balance, and increased stability**, as indicated in the central portion of the diagram.

The right side of the diagram further illustrates the functional benefits of a clay-based metatarsal implant. By providing biomechanical support to the forefoot, the implant allows the foot to regain a more natural rollover pattern during walking. This improved biomechanics reduces the need for compensatory trunk lean and promotes a more upright posture. Restoration of the forefoot lever arm also enhances walking efficiency and may reduce fatigue associated with prolonged ambulation.

Another key biomechanical aspect highlighted in the diagram is the **redistribution of plantar pressure following implantation**. After metatarsal amputation, plantar pressure patterns are significantly altered due to the absence of forefoot support. The pressure map shown in the lower left portion of the figure demonstrates that excessive pressure

often accumulates beneath the heel, as the body compensates for the loss of the forefoot load-bearing region. This abnormal loading pattern can increase the risk of tissue damage and ulcer formation, particularly in individuals with diabetes or peripheral neuropathy [1,21].

With the introduction of a clay-based implant, plantar pressure distribution becomes more balanced across the foot, as illustrated in the lower right portion of the diagram. The restored structural support allows the forefoot to participate again in weight bearing, thereby reducing excessive pressure at the heel and redistributing loads more evenly across the plantar surface. This balanced pressure distribution not only improves walking comfort but also decreases the likelihood of secondary complications such as pressure ulcers and tissue degeneration.

Beyond mechanical support, clay-based biomaterials may offer additional therapeutic advantages due to their unique physicochemical properties. Certain clay minerals exhibit inherent antibacterial activity, which may help reduce the risk of infection in implantable devices [11,28]. Furthermore, nanoclay-reinforced biomaterials can enhance tissue regeneration by supporting cell adhesion, proliferation, and differentiation. Studies have demonstrated that nanoclay scaffolds can promote angiogenesis and osteogenic activity, which are critical processes for successful tissue integration and healing [16,40].

The integration of clay-based implants into prosthetic design therefore represents a promising multidisciplinary approach that combines **biomechanics, materials science, and regenerative medicine**. By simultaneously addressing structural support, pressure redistribution, and biological compatibility, these advanced biomaterials have the potential to significantly improve functional outcomes for patients undergoing partial foot amputations.

In summary, clay-based implants offer a novel strategy for restoring gait mechanics following metatarsal amputation. As illustrated in Figure X, these implants can reestablish the forefoot lever arm, improve push-off during walking, and normalize plantar pressure distribution. In addition to enhancing biomechanical performance, the bioactive properties of nanoclay materials may support tissue integration and reduce complications associated with conventional implants. Continued research into the design and optimization of clay-based prosthetic systems is therefore essential for advancing rehabilitation strategies and improving mobility in individuals with forefoot amputations.

9. Bioactive and Biomechanical Benefits of Clay-Derived Prosthetic Implants

The development of advanced biomaterials has become a critical focus in modern prosthetic and orthopedic research, particularly for restoring biomechanical function following partial foot amputations. Among emerging materials, **clay-derived biomaterials and nanoclay-reinforced composites** have gained considerable attention due to their unique combination of **biomechanical strength, bioactivity, and multifunctionality**. These properties make clay-based materials promising candidates for next-generation prosthetic implants designed to restore structural integrity, improve gait mechanics, and promote tissue integration.

One of the most significant advantages of clay-derived prosthetic implants lies in their **enhanced biomechanical performance**. Clay nanoparticles, such as nanosilicates and halloysite nanotubes, can significantly reinforce polymer matrices by improving stiffness, tensile strength, and load-bearing capacity. When incorporated into prosthetic structures, these nanomaterials create composite systems that exhibit superior mechanical stability while maintaining lightweight characteristics. This reinforcement is particularly important in forefoot reconstruction, where implants must withstand repetitive loading during walking and distribute forces effectively across the plantar surface [8,36]. By strengthening prosthetic components, nanoclay composites help restore the structural support normally provided by the metatarsal bones.

In addition to improved mechanical properties, clay-based biomaterials offer **enhanced biomechanical compatibility with biological tissues**. Unlike traditional metallic implants that may cause excessive stiffness and stress shielding, polymer–clay nanocomposites can be engineered to more closely mimic the mechanical behavior of natural bone and connective tissue. This mechanical compatibility allows the implant to participate in physiological load transfer without creating abnormal stress concentrations in adjacent tissues. Consequently, clay-derived prosthetic implants may reduce the risk of implant failure and improve long-term functional outcomes for patients undergoing partial foot reconstruction.

Another important feature of clay-derived implants is their **bioactive surface properties**, which support biological interactions at the implant–tissue interface. Clay minerals possess a layered structure with high surface area and abundant charged sites, allowing them to interact with proteins, growth factors, and cellular components. These interactions can promote **cell adhesion, proliferation, and differentiation**, which are essential processes for successful tissue integration. Studies have demonstrated that nanosilicate particles can stimulate osteogenic differentiation in mesenchymal stem cells, indicating their potential to support bone regeneration and tissue repair [7,39].

The **antibacterial properties** of certain clay minerals provide an additional advantage for biomedical applications. Several naturally occurring clays exhibit broad-spectrum antimicrobial activity due to the release of metal ions and reactive chemical species. This antibacterial activity may help reduce the risk of infection in implantable prosthetic devices, which is a significant concern in orthopedic surgery and limb reconstruction [11,28]. By limiting bacterial colonization around the implant site, clay-derived materials can contribute to improved post-surgical healing and implant longevity.

Clay-based biomaterials also offer promising opportunities for **controlled therapeutic delivery** within prosthetic systems. The tubular and layered structures of halloysite nanotubes enable encapsulation of bioactive molecules, drugs, or growth factors that can be released gradually over time. This capability allows prosthetic implants to function not only as structural supports but also as therapeutic platforms that promote tissue regeneration and healing. Sustained drug release from clay nanotubes has been demonstrated in several biomedical studies, highlighting their potential for advanced regenerative applications [13,42].

From a biomechanical perspective, the integration of clay-derived materials into prosthetic implants can significantly improve **load distribution and gait mechanics**.

In cases of metatarsal amputation, the absence of the forefoot lever arm disrupts normal propulsion and leads to abnormal plantar pressure patterns. Clay-reinforced prosthetic components can help restore structural continuity in the forefoot, enabling more efficient transfer of forces during the stance and push-off phases of gait. This restoration of biomechanical function may improve walking efficiency, increase stability, and reduce compensatory movements such as trunk lean or excessive ankle dorsiflexion.

Furthermore, clay-based implants can contribute to **improved plantar pressure redistribution**, which is essential for preventing tissue breakdown and ulcer formation in high-risk patients, particularly those with diabetes. By recreating a supportive forefoot structure, these implants allow plantar loads to be distributed more evenly across the foot, reducing localized pressure concentrations that commonly occur after partial foot amputations [1,21]. Balanced pressure distribution not only enhances patient comfort but also plays a crucial role in preventing secondary complications.

The multifunctional characteristics of clay-derived biomaterials—combining mechanical reinforcement, bioactivity, antibacterial behavior, and therapeutic delivery—position them as a promising class of materials for future prosthetic and orthopedic innovations. Their ability to simultaneously address both **structural and biological requirements** distinguishes them from conventional implant materials that primarily focus on mechanical performance.

In summary, clay-derived prosthetic implants offer substantial advantages for reconstructive and rehabilitative applications. Their superior mechanical reinforcement capabilities support load-bearing function, while their bioactive properties promote tissue integration and regenerative responses. Additionally, their antibacterial and drug-delivery potential further enhances their clinical utility. These combined properties make clay-based biomaterials an attractive platform for the development of advanced prosthetic implants aimed at restoring gait function and improving long-term outcomes for patients with partial foot amputations.

10. Limitations and Challenges

Despite their advantages, clay-based prosthetic implants also present several challenges. Pure clay structures are relatively brittle and may lack sufficient mechanical strength for load-bearing applications [55].

Additionally, achieving uniform dispersion of clay nanoparticles within composite matrices remains a technical challenge [56]. Long-term biocompatibility and clinical validation also require further investigation.

In summary, while clay-based biomaterials demonstrate considerable potential for prosthetic implant applications, several challenges—including mechanical limitations, dispersion issues, long-term biological evaluation, manufacturing complexity, and regulatory requirements—must be addressed. Continued interdisciplinary research involving materials science, biomedical engineering, and clinical medicine is essential to overcome these limitations and fully realize the potential of clay-based prosthetic technologies.

11. Future Perspectives

Future research should focus on developing hybrid clay-polymer and clay-ceramic composites with improved mechanical and biological performance [57]. Advances in additive manufacturing and 3D printing may also enable the production of patient-specific prosthetic implants [58].

Furthermore, integrating bioactive molecules and smart sensor technologies into clay-based implants may improve therapeutic outcomes and implant monitoring capabilities [59].

In addition, future research should focus on improving the **cost-effectiveness and accessibility of prosthetic technologies**. Since clay minerals are naturally abundant and relatively inexpensive, clay-based composite implants could provide an affordable alternative to conventional metallic or polymeric prostheses. This may be particularly beneficial in low-resource healthcare settings where access to advanced prosthetic materials is limited.

Overall, the future development of clay-based prosthetic implants will require interdisciplinary collaboration among materials scientists, biomedical engineers, and clinicians. Advances in nanotechnology, biomaterials engineering, and additive manufacturing are expected to play a crucial role in optimizing the design and functionality of these implants. With continued research and technological innovation, clay-based biomaterials may become an important component of next-generation prosthetic systems designed to restore mobility and improve the quality of life for individuals with limb loss.

12. Conclusion

Metatarsal amputation significantly disrupts foot biomechanics and gait patterns. Clay-based biomaterials represent a promising alternative to conventional prosthetic materials due to their unique structural and biological properties. These materials demonstrate potential for enhancing implant integration, improving mechanical performance, and restoring gait function.

In conclusion, clay-based biomaterials represent a promising and innovative approach for the development of next-generation prosthetic implants aimed at restoring gait function following metatarsal amputation. Continued interdisciplinary research integrating materials science, biomedical engineering, and clinical practice will be essential to fully explore their potential and translate these emerging technologies into practical medical solutions that improve patient mobility and quality of life.

However, further experimental studies, clinical trials, and advanced biomaterial engineering approaches are required to fully realize the clinical potential of clay-based prosthetic implants.

Abstract **- Teaching a robotic arm can be unintuitive and difficult because the difference between natural movements of human limbs and the control of robotic manipulators can be far apart. Substantial training is often necessary in order to effectively operate such systems. This work shows the develop of an intuitive and easy to use interface for mapping human palm gestures to control the movement of a 5 axis robot, the Dexter ER2. The proposed vision-based system allows robotic arms to follow hand gestures by themselves in a three-stage methodology namely the gesture detections, gesture tracking and robotic manipulator controls. A model using deep learning is used for precise recognition of gestures so that the robot can give the impression of moving the limbs like the controller with a minimal cognitive load. For computing the trajectory and creating the joint movement, an inverse kinematic solver based on adaptive gradient descent is implemented for efficient and smooth convergence of joint angles for the desired end-effector positions. The interface has been successfully implemented, which means that the robot will follow gesture commands and will reach target positions. The proposed vision-based gesture driven control scheme of Dexter ER2 robot arm is validated by simulation and experimental studies. The very system used serial communication and guaranteed a continuous and lossless data stream between the controller and the computer. A detailed comparative analysis is also put forward in order to demonstrate the advantages of the proposed approach. Future work is to improve visual appearance with the graphical interface and to correct the latency issue in the real- time control.**

I. INTRODUCTION

A robotic arm is a technology imitation of human arm. Robotics has made its way into many industries, and changed the way in which tasks are done. While the control of robotic arms is a great advancement, advanced robotic manipulators are now operated and programmed more flexibly. A wide variety of such arms can be used. In the past, the most common way to control a robotic arm was via manual controls that included a joystick, a keyboard or a special control panel. Such a situation is also faced while working with a multi-degree-of-freedom (DOF) robotic arm where each joint of the robotic arm is to be actuated using a different control. Although a robotic arm is less like controlling a human limb than controlling a mobile robot, it is still considered to be much less intuitive than the more intuitive control of planar mobile robots. In the current field of study, the ultimate aim is to create an intuitive and easy to control mechanism, and that is cost-effective and requires less computational time through the use of natural motion of the human arm. Also, in order to make the control process simpler, various control strategies for robotic arms have been carried out such as gesture-based control [6], [7], [8], [9]. Using hand motions, users are able to interact with the robotic arm using hand pose estimated control which can be more simpler method to learn than conventional control techniques [6], [8], [9]. This methodology

can enhance accessibility and usability of robotic arms, which can be more adaptable and useful to a greater number of applications [6], [7], [9]. The main emphasis of this presented research work is an applied rather than theoretical. The present work puts focus on integrating techniques such as anthropomorphic control, gradient descent with adaptive learning rates for inverse kinematics (IK) and single-camera pose estimation into one unified visionbased control system. The novelty is the practical approach to apply these techniques with the intent to refine some practical interface, intuitive and costeffective, to control robotic manipulators in environments of constraints. By taking focus on usability, affordability and adaptability, this study fills the gap between the theoretical robotics and its practical implementation. Researchers have been researching on the concept of gesturecontrolled and pose-estimated controlled robotics, by going through various techniques and technologies to capture and process human hand gestures or various pose landmarks. One of the common methods is to use the cameras for detecting user hand movements and sending it as a control command for the robotic arm, this can be termed as Anthropomorphic control [10]. Anthropometric control of a manipulator is the control of a robotic arm or the manipulator in a manner that resembles or maps to control of natural motions of a human hand, i.e. anthropometric control is the design of such a manipulator system that the operator can intuitively control the motion of the end-effector by making motions or gestures of the arms or hands that the manipulator will follow [11]. As the field of robotics continues to develop, we might expect more innovative uses of robotics in the future.

II. LITERATURE REVIEW

Gupta et al. [7] proposed a continuous hand gesture recognition technique for human-machine interaction based on gyroscope sensor and accelerometer, and proved a high rate of classification and a high response rate of real- time. However, their method depends on the wearable device, which limits the natural user interaction and aims to sensor calibration, which limits its intuitiveness and expansion in the vision-based robotics control system. Atre et al. [8] built a low cost rule based robotic arm control system using web cam, Arduino and Bluetooth module. Tested in simulation, the system was limited by low level of precision, limited DOF and did not support AI integration or realtime control. In addition to this, Angulo et al. [12] demonstrated the application of stereo vision with robotic arm control at a critical application such as that of positioning near an explosive device. This shows how crucial the use of vision-based control is in hazardous environments. Solly and Aldabbagh [9], used a wearable hand glove controller system for a mobile robot system which uses flex sensors, accelerometer, Bluetooth module and radio module. The possibilities of the gesture mapping approach allowed robot navigation but were not suitable for precise manipulation tasks. The system, however, was experimentally verified and incurred a high cost as a result of the wearable hardware. Further, Altayeb [13] created a robotic arm finger control system, with a

webcam for simple vision thresholding, as well as Arduino, servomotor and buck converter. The system was experimentally validdated and provided a moderately priced solution, but was faced with limitation for scalability. Qin et al. [14] used the monocular RGB camera and imitation learning algorithm to allow real-time gesturebased teleportation of multi-fingered dexterous robots. The system showed good potential, but overcome with different challenges such as loss of tracking in fast motion and unreliable hand pose estimation, relatively high implementation cost. In addition, Terreran et al. [15] introduced a contactless interface for collaborative robots with an encouraging result using natural human-robot interaction. However, limitations are still present in having precises manipulation and robustness in different lighting and background conditions, which indicates the need for better visual processing and realtime gesture interpretation that can be improved. Suhaimi et al. [16] presented a control system for 4DOF robotic arm using Electrooculogram (EOG) and Electromyography (EMG) sensors which consist of a combination of EMG- based gaze estimation and image processes. The system requires the fusion of complex sensors and came with a very high cost. Moreover, Godoy et al. [17], proposed an affordable and EMGbased tele-manipulation framework for intuitive control of robotic arm-hand systems, where it was shown the improved task execution in dynamic environments using multimodal sensing. However, a certain dependence on EMG signals and predefined object affordances makes the system less adaptable and less generalizable for users, which suggests the need for more natural and flexible ways to interact with the system like vision-based gesture control. Ban et al. [18] proposed a persistent human machine interface for the robotic arm control using gaze and eye gestures to realize an high accuracy with little calibration for disabled humans. However the approach requires specialized eye tracking hardware restricting the accessibility and scalability of borderpressive control

systems

III. PROBLEM STATEMENT

Industrial robotic manipulators have become an integral part in the modern manufacturing, automation, healthcare, and research laboratories. These robotic systems are often programmed and controlled with the help of teach pendants, joysticks, keyboards and/or

complex programming interfaces. Although these control methods offer specific manipulation capabilities, users often need specific training, technical expertise, and a considerable amount of time to learn and effectively use them. As a result, the usability of robotic systems is only available to trained personnel, the accessibility to non- expert users is reduced and the speed of executing tasks in dynamic environments is reduced. Traditional robot programming methods also lack intuitive humanrobots interaction (HRI). Operators have to manually type in the commands or program for themselves to perform complex action tasks, which makes the process of interaction rigid and inefficient. In applications where the required adjustments need to be made quickly, involve a natural form of interaction or require real-time control, like for research labs, educational environments, collaborative robotics and fast prototyping, these traditional interfaces become inconvenient and inefficient. Furthermore, existing teach pendant systems tend to be bulky, hardwaredependent and be constrained by wired interfaces to limit operator mobility and flexibility. These limitations point out the necessity of more natural, intuitive and user-friendly control mechanisms that enable communication with robots in a manner that is very similar to natural human actions. Recent technological developments in the fields of computer vision, machine learning, and human-computer interaction have made it possible to create gesture recognition systems that are able to interpret human hand movements through the use of cameras. Visionbased gesture recognition provides a promising solution to the traditional robot control interfaces as it enables the users to interact with robotic systems using simple hand gestures without any knowledge of controllers or programming of the robotic system.

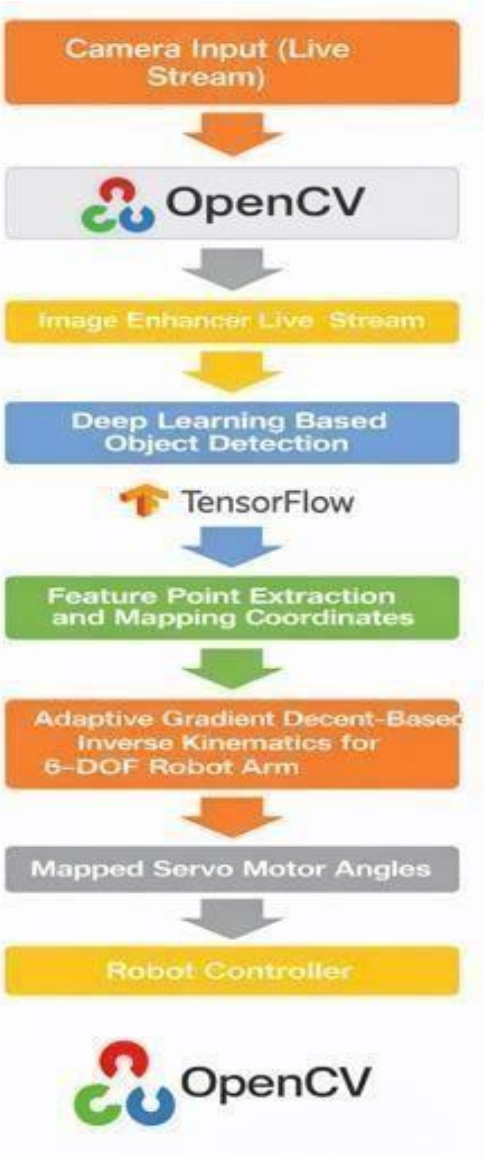
IV .PROPOSED SYSTEM

The system is a step-by-step process, as shown in Figure 6: First, the data of live stream is processed by the camera and then this data is enhanced by using Open Source Computer Vision Library (OpenCV) functions. These image enhancement techniques are used to get more detailed and clear images from the webcam feed, which will make it easier to identify and track hand movements accurately. In real world situations the feed from the camera is subject to a wide range of sources of noise and dynamic environmental influences such as lighting variations, motion blur caused by sudden movements of the hands, and sudden change in the background. These factors can greatly impact the quality of visual input, doing so will make it rather difficult to reliably detect and track hand gestures.

In order to solve these kind of challenges the proposed system implements a set of image Enhancements, such as noise filtering, adaptive Contrast Enhancement and Motion Blur Compensation .incorporation of these enhancement techniques helps the robustness and responsiveness on the vision-based control framework in real-time under dynamically and changeable conditions.

Next, the improved live stream data is sent for deep learning based object detection with the help of the MediaPipe, a crossplatform framework to build multimodal applied ML pipelines. In the object detection method of deep learning, the hand key points are estimated by its advance hand tracking model. This model captures and monitors 21 landmarks on the hand, with accurate spatial information on the location of each point. Among those landmarks, we are concentrating on landmark 8, which is the tip of an index finger. The x and y coordinate of this landmark are extracted and this person actually represents a pixel location in this video frame. To get depth information
(the z-axis), we take an

Fig 1: control-system of vision based control-flow chart



average of the Euclidean distances from keypoint 9 (base of the middle finger) to the keypoint 8 (tip of the index finger) and from keypoint 9 to keypoint 12 (tip of the middle finger). These distances were selected after a lot of testing since it turned out to be more stable in comparison to distances between other pairs of

landmarks, providing more consistent and accurate depth estimation.

V. METHODOLOGY

The proposed system implements a vision-based gesture control mechanism to operate a 5-axis robotic arm, Dexter ER2, through natural human hand movements. The methodology is designed to enable intuitive interaction between humans and robotic systems by translating palm gestures into corresponding robotic arm actions. The overall system architecture consists of several sequential stages including image acquisition, gesture detection, gesture recognition, trajectory generation, and robotic arm control. These stages work together to ensure accurate gesture interpretation and smooth robotic motion.

In the first stage, real-time image acquisition is performed using a camera that continuously captures video frames of the user's hand gestures. The captured frames are processed using computer vision techniques to detect the presence of a hand within the frame. Image preprocessing operations such as frame resizing, normalization, and background filtering are applied to improve the quality of the captured data. These preprocessing steps help reduce noise and enhance the visibility of the hand region, enabling more reliable gesture detection. Following detection, the system performs gesture tracking and recognition. A deep learning- based model is employed to identify and classify different palm gestures from the processed frames. The model is trained using a dataset containing multiple hand gesture samples to improve recognition accuracy. Feature extraction techniques are used to identify key characteristics of the hand such as finger positions, palm orientation, and movement direction. The trained model then classifies the detected gesture into predefined categories, each representing a specific robotic arm movement command. This stage allows the system to interpret human gestures effectively and convert them into control signals.

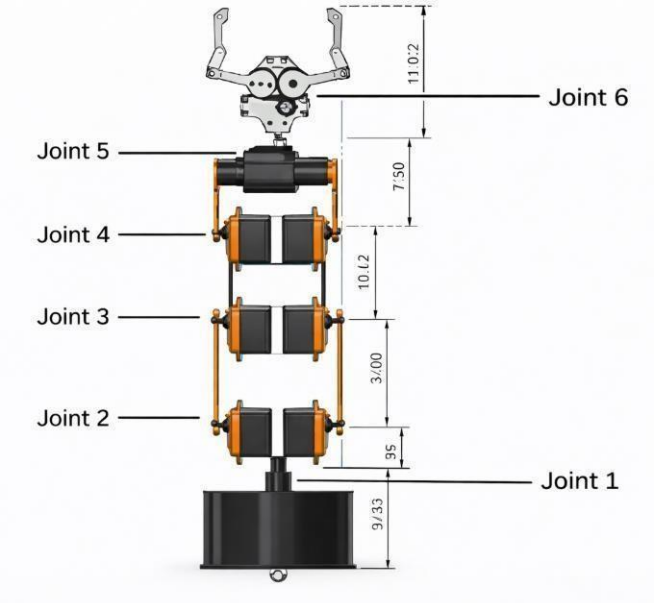


Fig. 2. Joints and links in Dexter ER2.

Upon recognizing a gesture, the system gets the desired pose of the robotic arm end-efficer. To accomplish this, an inverse kinematics solver, which is built on adaptive gradient descent is adopted. The inverse kinematics algorithm will be used to determine the joint angles which must be used to move the robotic arm to the required position based on the gesture command. The adaptive gradient descent methodology guarantees the smooth convergence of joint parameters and reduced complexity of computations. This allows the efficient planning of trajectory and guarantees accurate movement of robots. Joint parameters are calculated and control commands sent to the Dexter ER2 robotic arm via a serial communication interface. The communication protocol helps maintain reliable and constant data flow between the computer and the robot controller, and the protocol ensures that there is no loss in the data flow. Lastly, the suggested system is tested by simulation as well as real-life testing. Gesture commands of different types are tested to test the responsiveness and precision of the robotic arm. The obtained experimental findings indicate that the robot is able to follow the gestures of the user and arrive at the desired target positions. The system offers an easy to use form of human-robot interaction interface which minimizes the complexity of the conventional robotic control systems and enhances ease of use and efficiency. Next generation design of the system is to provide a better graphical user interface which can be used to interact with the system and to minimise the system latency so that real time control of the robots can be realised.

VI. COMPARATIVE ANALYSIS

Table 1 provides the complete comparative analysis of recent gesture controlled robotic arm system presented in [8], [9], [12], [13], [14], [15], [16], [19], [21] and [22],
by highlighting some of the key aspects as sensor used, hardware platform, Artificial Intelligence Model, Limitation of the system, Relative Cost and Remark. The following summary of Table 5 points out the novelty and efficacy of the proposed approach. • Some existing approaches only conform to simulation, which do not possess real-time control ability, such as [8], [15], [21], and [22]. In contrast the proposed work shows real- time control based on an experimental design, making a link between the theory and experimental implementation. In [16] the sensor fusion technique is being used which consists of complex and expensive hardware configuration. The approach proposed here makes this simpler by using a single RGB camera, which provides aleyenrable and easy-todeploy solution that in turn does not impair functionality. Rare previous researches use wearable devices for gesturebased

control [9], [16] which might affect user's comfort and complicate the system. The proposed method removes this dependency by using a vision only system to interpret hand gestures without any physical attachment. The following are true for the applications of the scales. To mitigate this, the proposed system makes use of a 6-DOF robotic arm combined with an adaptive gradient descent based IK solver to aid in a responsive control system. Another problem in [15], [19], [21] is they are sensitive to noises and have a low adaptability to environmental changes. The proposed model solves the above problems by a deep learning-based gesture recognition model which is both noise resilient as well as diverse environmental variations for a robust performance in real-world environment. This comparison clearly puts into perspective the practical advantages of the proposed work in terms on intuitive control, lowcost implementation, robust performance in a noisy and dynamic environment and real-time validation though both simulation and physical experimentation.

VI: RESULT AND DISCUSSION

This section provides the performance evaluation of the proposed system with the help of both simulation and experimental evaluations. The simulation analysis of the proposed system is performed in the Gazebo and PyBullet simulators. Further, the experimental setup of development is presented followed by the performance and robustness of the proposed system.

A: SOFTWARE AND HARDWARE USED :

This is the section, which describes the hardware and software which is used in the simulation and experimental studies. The hardware parts of the experimental setup include a 6 DOF robotics arm which isa Dexter ER2 Manipulator, ATmega328P based Controller, personal computer (PC), Servo Driver. The software components used are PyBullet simulator, Gazebo simulator, MediaPipe framework, OpenCV library, Robot Operating System 2 (ROS2), Arduino Integrated Development Environment (IDE) and for Computer-aided design (CAD) model development and Unified Robot Description Format (URDF) developing Fusion360 was used. The detailed description of hardware and software components are listed and described in table 3 and table 4 respectively. This section provides the performance evaluation of the proposed system with the help of both simulation and experimental evaluations. The simulation analysis of the proposed system is performed in the Gazebo and PyBullet simulators. Further, the experimental setup of development is presented followed by the performance and robustness of the proposed system. B. SIMULATION RESULTS : The provided simulation and analysis in this work has been performed in two different approaches in order to confirm the efficiency of proposed framework. The first one used Gazebo simulation environment with the integration of ROS2 Humble distribution of robotic modeling and control. In the second used the PyBullet physics engine that came to simulate the Rigid body dynamic and interaction. 1) GAZEBO SIMULATION According to the first validation strategy, using Gazebobased simulation The URDF file was created to specify the kinematic structure, link dimensions and

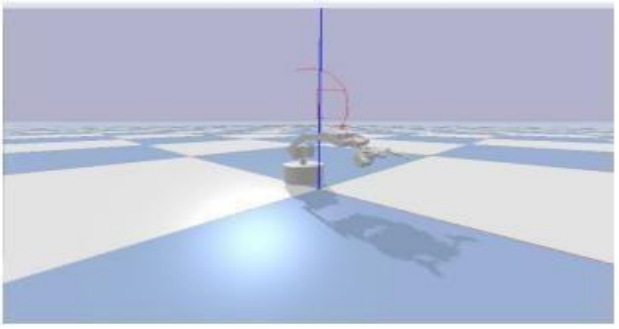

Fig. 3. Robotic arm simulation physical characteristics of the Dexter ER2 robotic manipulator.

The URDF model has been developed in Fusion 360 that is a popular CAD application that allows focusing on the accurate modeling and assembling of robots.

Tool Platform	Purpose
PyBullet	Python-based robotics simulator used to test robot control and motion algorithms.
MediaPipe	Framework used for real-time object detection and tracking.
OpenCV	Computer vision library used for image processing and edge detection.
Gazebo	3D robotics simulator used to test robots in virtual environments.

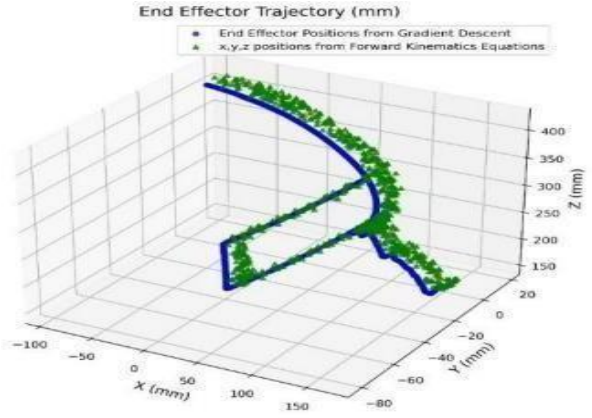
ROS2 (Humble)	Middleware used for robot communication and control.
Fusion 360	CAD software used to design robot parts and create URDF models.
Arduino IDE	Programming platform used to develop and upload code to Arduino boards.

Table I Development tools and platforms used

After finishing with the model in Fusion 360, the URDF file was exported, and later, it was imported into Gazebo simulation environment. This allowance of realistic visualization and simulation of the behavior of the robot through the ROS2 framework was made possible by this

Fig 4: Dexter ER2 spawned in Gazebo environment.

To prove the efficiency of the suggested IK solution, the algorithm of adaptive gradient descent will be tested as a ROS2 Python node to calculate the joint angles of the 6- DOF Robot Arm in order to reach a required end-effector location and orientation. This node is strictly tested in Gazebo simulation environment where its performance is tested in different configurations with an iterative and a trial and error approach. By combining an IK solver with the Gazebo simulation, it is possible to control and visualize the robotic manipulator in real-time using ROS2 controllers and show the responsiveness and potential usage of the offered approach in the simulated setting.
2) PyBullet SIMULATION A second validation strategy is the use of the program (SIMULATION) which used the PyBullet physics engine as its framework to provide an effective and robust way of simulated dynamics of a rigid body. Here the suggested adaptive gradient descent-based IK solver is then used in calculating the joint angles to be used to reach the desired set of end-effector positions in terms of their Cartesian coordinates (x, y,z). The computed joints angles were later used to revise the setting of the simulated manipulator in the PyBullet environment. Figure 8 shows the simulation results that indicate the viability and the effectiveness of the proposed control scheme in the dynamic conditions. FIGURE 4. PyBullet simulation. 3) PICK-PLACETASK Figure 9 shows the performance of pick-andplace task with the suggested 6-DOF robotic arm using the proposed gesture-based control mechanism. This exercise is an exercise in validation where we test out the practicality and easier user-friendliness of the system in a scenario-based test. The findings depict that real-time human hand gesture can be successfully converted into accurate robotic manipulator motions that allow accomplishment of tasks with accuracy and efficiency and that the system can be applied effectively to the real-life environment in industrial automation, assistive robotics and dangerous environment operations. In order to assess the performance of IK solver included in the control loop, the end-effector positions obtained with the help of calculated joint angles were compared to the desired positions provided in the beginning. Such comparison makes the accuracy of the IK algorithm susceptible to a thorough quantitative analysis. Data visualization



represented by plotting of the results was subsequently

Fig. 5. End effector trajectory

done as shown in Figure 10. The evaluation allowed finding out a variety of results: in some cases, the calculated end effector position based on the desired coordinates was obtained with deviations of about 1 to 5 millimeters, and in some others, it was in alignment of almost exactly and along the x, y, and z planes. These differences are attributable to the difficulty of solving IK to redundant and nonlinear systems, in which accuracy could be affected by numerical approximations, the convergence properties of an algorithm, and approaches to kinematic singularities. Nonetheless, the overall outcomes justify the trustworthiness and the accuracy of the adaptive gradient descent-based IK solver-based control scheme in a system of dynamic gestual control driven application setting.

C. EXPERIMENTAL RESULTS

The given section is the experimental validation of the proposed system, the integration of a Dexter ER2 6DOF.

robotic arm having a controller built on the ATmega328P. This integration makes the setup a dynamic one that has the ability to track a moving hand with a monocular camera. The target in this set up is a hand of a person and this is identified by a monocular camera attached to a laptop. The robotic arm is initially operated in an idle mode and it imitates movements of the hand in real time. The framework has a grip on an advanced learning approach based on gesture extraction to derive real-time finger positions in a video conveyed live. Those coordinates are optimized with the help of the adaptive gradient descent based on the IK algorithm specifically designed to use the kinematics of the robotic arm. It is possible using it to detect hand gestures, which can be converted to data related to the angles of the joints, so of the manipulator. This joint angle control modeled as that the robotic arm can mimic the hand gesture and movement. Figure 11 illustrates hardware connection of a given experimental set-up. Anthropomorphic control is enabled by the following PC containing a control algorithm made up of the OpenCV library, MediaPipe, and ROS2 framework to combine software tools with the Dexter ER2 Manipulator. The experimental proof of the proposed control scheme based on a vision-based gesture-driven is shown in Figure 12. FIGURE 6. Comparison of desirable and actuated pose through data visualization.

***Abstract*— The rapid growth in global logistics demands intelligent solutions that can deliver container security and safety features along with real-time monitoring. Hence, in this paper, a novel IoT-based 3D Digital Twin container security and safety system for real-time environment monitoring is proposed. The proposed system utilizes various sensors for real-time measurement of parameters such as pressure, temperature, humidity, vibration, and GPS location using a microcontroller such as ESP32. The sensor data is sent in real-time to the cloud platform using Google Firebase. A web-based system is proposed that utilizes a 3D digital twin for representing the physical system in a digital environment. The proposed system ensures better transparency in the system and minimizes damage to the cargo during transportation. The proposed system utilizes a priority-based system for better detection capabilities by giving due importance to certain parameters. The proposed system is implemented and tested for real-time operations in a cyber-physical system.**

Keywords—Digital Twin, Internet of Things (IoT), Smart Logistics, Container Security and Safety, Real-Time Tracking System, Sensor Integration, Cloud Computing.

I. INTRODUCTION

With the increase in trade, there is a need to develop an intelligent container monitoring system, which can ensure security, safety, and monitoring of goods carried in the containers. Existing container management systems have adopted location-based monitoring systems, which are not effective in monitoring environmental conditions, causing damage, security issues, and wastage of resources. Recently, IoT technology has shown much potential, which can lead to the creation of smart spaces using both physical and virtual components, called "digital twin," which can be used for real-time monitoring and decision-making.

The main idea of this project is to develop an IoT-based container security system using a concept of "3D digital twin." Parameters such as pressure, temperature, humidity, vibration, and location of the container can be monitored using IoT platforms such as ESP32, which can be sent to the cloud using services such as Google Firebase, thereby increasing the efficiency, security, and intelligence of the supply chain management process..

However, owing to the complexities involved in the current supply chain logistics, it has become a challenge to ensure the integrity and security of the goods in transport. For instance, containers carrying food items, medicine, and other high-value items are more vulnerable to environmental factors, mishandling, and unauthorized access during transport. However, the current monitoring systems are unable to offer real-time data, which has become a hindrance in addressing the issues involved in the transport process. However, the development of IoT technology has created an opportunity to bridge the gap between physical assets and the current virtual monitoring systems. This can be achieved through the real-time monitoring of assets using a virtual system, which can help the logistics operators in monitoring the assets remotely, hence addressing the issues involved in the transport process, including the potential risks involved in the process. In the proposed project, a series of sensors can be linked

using an embedded system like ESP32, which can be used to obtain real-time data, which can be synchronized using cloud technology like Google Firebase.

In this paper, a comprehensive IoT-based container monitoring system is proposed, taking into account the concept of a digital twin. In this proposed system, data acquisition is done using various sensors with ESP32 hardware, and cloud storage is done using a cloud platform called Google Firebase. The contributions of this proposed system are priority-based risk detection, visualization using a digital twin concept, etc. The structure of this paper is as follows: system architecture, methodology, experimental results, and conclusion.

The rest of the paper is organized as follows: the system architecture and design methodology will be introduced in the next part, and then the implementation and experimental results will be provided, and at last, the performance analysis and conclusion will be presented to prove the effectiveness of the proposed IoT-based 3D digital twin container monitoring system.

II. LITERATURE SURVEY

With the recent developments in Internet of Things (IoT) and digital twin technology, smart logistics, and container monitoring systems have witnessed a significant impact. Various researchers have presented different frameworks using digital twin technology to enhance visibility in logistics environments. Wang et al. have presented an IoT- and digital twin-enabled framework to enable asset tracking in safety management, where assets are continuously monitored to detect abnormal situations in real-time using cyber-physical models. Various researchers have presented studies using digital twin-based maritime logistics to identify how digital twin technology can enhance awareness, analytics, and intelligent decision-making in logistics infrastructures.[1]

Researchers have presented studies using hybrid IoT monitoring architecture to enable monitoring of internal container conditions such as temperature status using container logistics, which can enhance the ability to overcome the limitation of a GPS-based tracking system.[2] Furthermore, a digital twin-based logistics platform has also been presented to optimize energy consumption in automated container terminals [3].

However, various smart container monitoring systems have only focused on optimization of infrastructure or monitoring, where there is a lack of integrated security monitoring using multi-sensor security monitoring functions, interactive visualization, etc [4] thus, there is a need to develop a comprehensive real-time digital twin-based container security system. In addition to this, recent research also proves the application of IoT and digital twin technology in the development of logistics monitoring system [5]. Zhao et al. have proposed an IoT framework for digital twins in the field of real-time safety monitoring [6].

Similarly, [7] Lu et al. have proposed a digital twin system for automated container terminals for better visualization of the system. However, this is more focused on infrastructure management. [8] Zhou et al. have proposed a smart maritime logistics system using digital twin and data analytics technology for better decision-making in logistics operations. Similarly, Wang and Hsu have proposed an IoT-based cargo monitoring system for better reliability in the monitoring system. [9] Abbas et al. have also discussed the application of digital twin technology for better visibility in the supply chain. However,[10] there is a lack of integrated multi-sensor monitoring with 3D visualization and priority alert in logistics operations, as discussed in the proposed system.

III. PROPOSED SYSTEM

The system proposed here is a framework of an IoT-based container security system with monitoring, and a 3D digital twin is included in the proposed system. In the proposed system, different sensors are used to collect data on pressure, temperature, humidity, vibration, tilt, and GPS location.[11] These sensors continuously monitor the condition of the container while it is being transported. The data collected by the sensors is then sent to the cloud platform through a microcontroller like ESP32, and the data is then processed in real time.

A web application is used to create a 3D digital twin of the real-world container, and the real-time[12] parameters of the container can be viewed remotely. The proposed system has a priority-based alert system, and the parameters like pressure are given the highest priority, followed by temperature and humidity[13]. The proposed system is efficient, effective, and secure, and it provides a cyber-physical system for the security of the container.change the headlight state to low beam or not to avoid any glare and to improve safety while driving.[14]

The hardware used to implement the proposed system is given in Table I. It is seen that various sensors, microcontrollers, switches, and other electronic devices are used to implement the proposed system.[15]

The proposed architecture consists of IoT sensors, embedded systems, cloud connectivity, and a digital twin interface for monitoring in 3D. The data obtained by the ESP32 is then sent to Google Firebase for synchronization and efficient security and logistics management.

The architecture of the system, as proposed in this paper, is based on a four-layer structure. These layers are the sensing layer, processing layer, cloud layer, and visualization layer. The sensing layer includes temperature sensors, humidity sensors, pressure sensors, vibration sensors, tilt sensors, and GPS sensors. These sensors are used for the continuous monitoring of the containers. The processing is carried out by an embedded controller, as ESP32.

The cloud layer is based on Google Firebase for the storage and synchronization of the data in real time. The visualization is carried out by a web interface for a digital twin in 3D for the monitoring of the containers in real time and automated alerts based on specific priority levels.

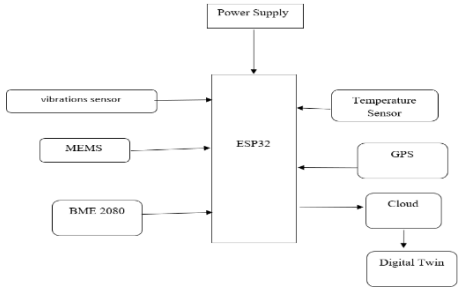

Fig. 1. Block diagram of the proposed Digital Twin-IoT based system.

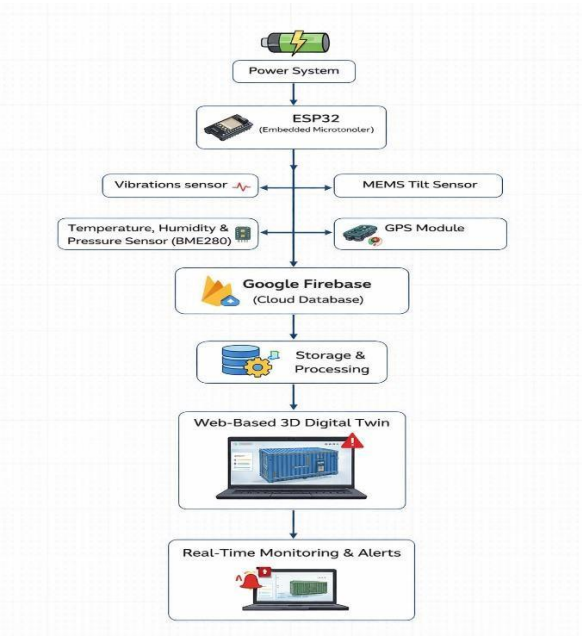
TABLE I. DEVICES USED IN THE PROPOSED SYSTEM

Name of the Device	Type of Device
ESP32 DevKit	Microcontroller
NEO-6M GPS Module	Positioning Sensor
SW-420 Module	Motion / Impact sens
BMP280	Atmospheric sensor
DHT11	Environment sensor
Tilt Switch Module	Orientation sensor
Power Supply	Power Source
Connecting Wires	Electrical Connecto

A) System Architecture

The architecture of the proposed container monitoring system is based on the layered IoT-based cyber-physical architecture, in which the integration of the data collected from the sensor, the processing of the collected data, the communication of the data with the cloud, and the visualization of the data are carried out. The sensing layer of the proposed container monitoring system comprises a vibration sensor, a MEMS sensor for tilt measurement, a BME280 sensor for environmental measurement, and a GPS module for location tracking. The data collected from the sensor is sent to the central processing unit, which is the ESP32 module. The data is sent through a wireless medium. A regulated power supply is connected to the proposed container monitoring system for the supply of power. The data collected from the sensor is sent through a wireless medium and transmitted to the cloud platform, Google Firebase. The cloud platform is connected to the application layer, in which a web-based 3D digital twin is created

The system architecture, as proposed here, also has cloud analytics and digital twin modeling. In the proposed system, the data is collected with the help of various sensors connected with the ESP32 module. Then the data is sent to the cloud with the help of various wireless communication protocols. Once the data reaches the cloud platform, data visualization, abnormality detection, and historical data analysis are performed. Also, the digital twin is created. The digital twin is the virtual version of the system. With the help of the digital twin, we are able to simulate the performance of the system based on the environment. Also, the proposed system is scalable; this means that other modules for the sensors and the analytics system can



also be added without affecting the performance of the system.

Fig. 2. Workflow of the proposed digital-twin IoT-based real-time 3D logistics tracking system

B) Digital-twin IoT-Based Container System

The Digital Twin system, which is an IoT-based system, creates a digital representation of a real-world environment through real-time data obtained through sensors integrated into a cloud platform. This system allows continuous monitoring, prediction, and

optimization of the system through a digital representation of the real-world system.

The framework of the proposed digital twin would use data from ESP32 sensors, combined with cloud analytics, to enable real-time system simulation. This would help to achieve condition monitoring and predictive maintenance using historical data, as well as current data. This would help to effectively manage a system remotely.

C. Container Security System with Priority-Based Mechanism

In the proposed container security system, the priority-based monitoring technique is used for efficient safety and resource usage. In the proposed container security system, sensor data is used from the vibration sensor, temperature sensor, MEMS sensor, environmental sensor, and ESP32 controller for efficient monitoring of the container security system. The events are classified based on various levels of priority based on the severity of the events such as critical, warning, and normal states.

Thus, a complex container security system will be proposed, utilizing IoT technology and including a digital twin visualization system. In this system, different sensors will be deployed inside the container, including pressure sensors, temperature sensors, humidity sensors, vibration sensors, and GPS sensors. Then, the data will be sent to a cloud-based Firebase database. Following this, a web interface will be used to create a 3D visualization of the container, referred to as a digital twin. In addition, a priority-based system will be included in the proposed system, with pressure, temperature, and humidity having a weighted priority, i.e., pressure > temperature > humidity. Then, notifications will be sent automatically in case there is a probability of security breaches, changes in the environment, and improper handling of the containers. The results of the experiment have shown that the proposed system is accurate in tracking the status of the containers, which will help in predicting potential hazards.

D. Decision Logic and Real-time 3D Control

The proposed system would also have an intelligent decision logic module, which would be integrated with the real-time interface of the 3D digital twin. The proposed system would also have the ability to monitor the conditions of the container through sensors such as pressure, temperature, humidity, vibration, tilt, and location, which would be obtained through the ESP32 module and then sent to the Google Firebase cloud platform in real-time.

The proposed intelligent decision logic module would compare the obtained data with the threshold values, after which the priority level would be assigned according to the severity of the obtained risks, wherein the pressure would have the maximum priority, followed by temperature and humidity changes. Once the abnormalities are obtained, alerts would also be sent automatically according to the changes in the real-time interface of the 3D digital twin.

The real-time interface of the proposed 3D digital twin would also be utilized to visualize the conditions of the container, wherein the user can obtain a better understanding of the environmental conditions, obtain knowledge of potential risks, and take necessary precautions in real-time through the proposed intelligent decision-making algorithms, which would enhance the safety of the container through the proposed system.

TABLE II. DIFFERENT INPUT CONDITIONS TO CONTROL 3D MODEL

Sensor Data	**3D Model Output**	**Inference on 3D Model (Output)**
Normal range values	normal green status	Safe operating condition; no action required
Moderate deviation in temperature / humidity	highlighted in yellow warning state	Environmental variation detected; monitoring required
High pressure, excessive vibration, or tilt anomaly	displayed in red alert state with warning notification	Critical risk detected; immediate intervention required

E. Advantages of the Proposed System

The proposed system allows for the monitoring of the containers in real-time with enhanced security using the IoT technology and the use of the 3D digital twin interface for the monitoring of the containers:

- Allows for the early detection of risks
- Providing priority-based alerts, the enhancement of the transparency of the system
- Minimization of the damage of the cargo, and the efficient management of the data using the cloud for the efficient operation.

The proposed system allows for the monitoring of containers in real-time with increased security using IoT technology and the use of a 3D digital twin interface for monitoring the containers.

I. EXPERIMENT AND RESULT

A. *Experimental Setup*

The experimental setup has been created with the aim of validating the efficacy of the proposed IoT-based container monitoring system and digital twin. The hardware prototype of the proposed IoT-based container monitoring system and digital twin consists of different sensor devices like temperature, humidity, pressure, vibration, tilt, and GPS sensor, connected with ESP32 for real-time data acquisition.

A regulated power driver circuit is necessary for the proper functioning of the entire proposed IoT-based container monitoring system and digital twin. The data is wirelessly transmitted through the Google Firebase cloud platform, used for data storage and processing. The web application is used for data acquisition from the Google Firebase cloud platform and real-time 3D digital twin update. Various environmental conditions like vibration, temperature, and tilt were artificially created for the experimental setup of the proposed IoT-based container monitoring system and digital twin.

The experiment employs the use of real-time modules and a 3D simulation environment. The latter is connected with the system for the validation of its responsiveness. The data is entered into the system by the sensor module and then processed by the unit. It is mapped onto a digital model. After this, disturbances are introduced for the accuracy, synchronization, and adaptability of the system.

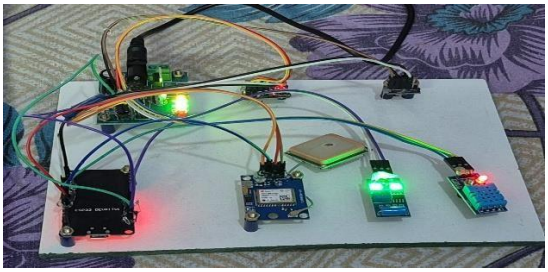


Fig. 3. Hardware Implementation of proposed system

B. *Experimental Result*

The results obtained from the experiments show that it is possible to effectively integrate the sensor data with the 3D model, thus allowing accurate real-time monitoring as well as interference detection. Moreover, it was also evident that it is possible to effectively map the sensor data to the virtual model, thus allowing accurate visualization of system performance. When there is controlled interference, it is also evident that it is possible to effectively visualize the interference zones, thus updating the 3D model. Additionally, it was also evident that there is stability in the synchronization of the sensor data with the digital environment, thus showing evidence of the reliability of the system.

When conducting an analysis of the accuracy of the system, it was also evident that there is an improvement in terms of efficiency in detecting anomalies, thus showing accurate visualization of system performance. When conducting the experiments, it was also evident that it is possible to achieve stable performance, thus showing evidence of reliability. From the experiments conducted, it is evident that it is possible to effectively enhance situational awareness, as well as reliability, through accurate visualization of system performance. The various testing scenarios, along with the corresponding output, are summarized in Table III. The results of a real-time testing of the proposed digital-twin IoT based container security system via a container prototype are provided in Fig. 4.

TABLE III. SCENARIOS WITH VARYING DISTANCE AND CNN DETECTION AND THEIR CORRESPONDING OUTPUT

Scenario	**Sensor Range**	**3D Model Output**	**Scenario Description**	**3D container State**
Scenario 1	Temperature: 20–30°C, Distance Sensor: Stable (0–5 cm variation)	Smooth real-time visualization with no alerts	Sensors detect normal environmental conditions and no external disturbance	Stable and Secure
Scenario 2	Temperature: 30–40°C, Vibration Sensor: Moderate fluctuation	Highlighted warning zone displayed on 3D model	Small external disturbance or partial obstruction detected near container	Warning State
Scenario 3	Temperature: >40°C, Motion/Vibration: High variation	Red alert visualization with flashing interference region	Significant intrusion or abnormal activity affecting container safety	Critical / Alert Mode

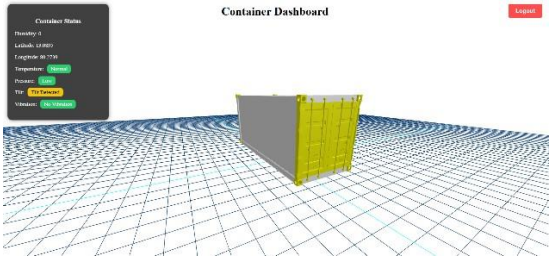

Fig. 4. Real-time testing of the proposed Digital-twin IoT 3D-container security system using a container prototype.

V. CONCLUSION

The proposed Digital Twin IoT-based container security system with priority-based monitoring and real-time 3D control is an efficient solution for intelligent container security management. The use of IoT technology, cloud computing technology, and digital twin technology in container security management allows for the continuous monitoring of environmental and operational parameters and the simultaneous virtual control of a physical container. The decision logic module is an intelligent module of the system, which uses the analysis of sensor data and generates a response based on the level of the threat. Real-time 3D control is a powerful tool for container security management, which allows for the observation and detection of any kind of interference in container security. The experimental evaluation of the system is a successful approach for the identification of normal, warning, and critical states of container security management with increased accuracy and faster monitoring times. Priority-based container security is an optimized solution for resource management.

In addition to this, scalability, accessibility, and the secure management of data are also enabled through this kind of architecture. This is why it is applicable in the field of smart logistics, port, and industrial asset management. This implies the existence of a bridge between the physical world and the virtual world. This is enabled through the integration of IoT analytics and digital twin modeling. This can also be extended in the future through the incorporation of predictive analytics with the aid of AI, etc.

ABSTRACT — Large retail environments often create navigation difficulties due to complex layouts and extensive product availability.Because of their intricate layouts and wide selection of products, large retail spaces frequently make navigation challenging. In order to increase in-store productivity, this paper introduces SmartStore Navigator, an intelligent indoor navigation and shopping assistance system. For product comparison, optimised path guidance, and product localisation, the system offers a digital store map. To lessen the checkout time, it integrates a self-billing system that uses barcode scanning. Accessibility is improved by using multiple input methods, such as text, voice, and image recognition. The user experience is enhanced by extra features like budget tracking, predictive recommendations, and crowd-aware navigation. Store optimisation and inventory control are supported by a management dashboard. The suggested solution increases customer satisfaction, decreases time consumption, and improves shopping efficiency.

I. INTRODUCTION

Retail spaces have grown larger and more diverse, which means finding what you need isn't always easy. Shoppers often end up wandering through aisle after aisle, especially during busy periods, and that can turn what should be a quick trip into a frustrating experience. Even with today's fast-moving digital innovations, most physical stores still don't have smart systems that help customers locate products or navigate efficiently.

Online shopping, on the other hand, makes life simple—search bars, filters, personalized suggestions, smooth checkout. Those perks rarely exist in brick-and-mortar stores. One lingering pain point? Checkout lines. Waiting for billing at crowded counters can eat up time and sour the entire shopping experience.

That's where SmartStore Navigator comes in—a smart, all-in-one retail solution built to close this gap. It merges indoor navigation, intelligent product search, and automated billing into one seamless system. Shoppers can pull up a digital store map on a web interface to pinpoint products and follow the fastest route to them. And when it's time to pay, they simply scan item barcodes with their phones or smart carts. Each scan adds to a virtual cart, updates the total bill instantly, and cuts out the need to stand in line at the register.

By blending indoor mapping, AI, and self-service tech, SmartStore Navigator makes shopping faster and more convenient, ultimately boosting customer satisfaction. It also helps retailers behind the scenes with improved inventory tracking and insights into shopping behavior—a well-rounded solution for the next generation of smart retail.

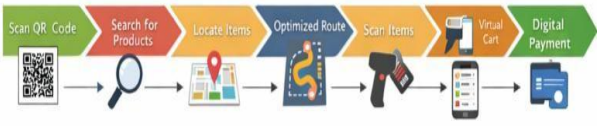

Fig.1-Workflow of SmartStore Navigator

II. LITERATURE SURVEY

A. Indoor Navigation Technologies

Many researchers have looked into indoor navigation systems designed to help people find their way through complex spaces like shopping malls or large retail stores. Technologies such as Bluetooth beacons, Wi-Fi positioning, and RFID are commonly used to locate users inside buildings. Since GPS signals often don't work indoors, these systems step in to guide users around and provide location-based assistance.

B. Smart Retail Systems

In the world of smart retail, the focus is on blending digital tools with physical store experiences. Current systems often offer things like product details, special offers, and personalized recommendations. The goal is simple: make shopping more engaging, convenient, and enjoyable for customers.

C. Artificial Intelligence in Retail

Artificial intelligence has become a game-changer in retail, especially for recognizing products and personalizing recommendations. With image recognition, shoppers can identify items by snapping a photo, while machine learning tools study browsing habits and past purchases to suggest products tailored to each customer's preferences.

D. Smart Billing and Automated Checkout Systems

New technologies in retail have brought about smart billing systems that speed up the checkout process and boost efficiency. Methods like barcode scanning, RFID-based billing, and cashier-less checkout let shoppers scan their items and get an instant bill. By cutting down on manual steps and wait times, these systems improve the whole shopping experience. However, many of them are still costly or work only in specific types of retail settings.

E. Limitations of Existing Systems

Even with all these advances, most current solutions focus on just one thing—whether that's indoor navigation, product recommendations, or checkout automation. What's missing is an all-in-one platform that brings together navigation, product discovery, predictive insights, and smart self-billing in a single streamlined system.

F. Research Gap and Motivation

To fill this gap, the SmartStore Navigator is introduced as a unified platform combining multiple intelligent features—like indoor navigation, smart product search, automated billing, and analytics tools—designed especially for modern retail spaces. The aim is to deliver a smoother, more efficient shopping journey by integrating all the key functions shoppers need into one cohesive system.

III. PROBLEM DEFINITION

Shopping in huge retail spaces—like supermarkets and hypermarkets—can feel more like running an obstacle course than a quick errand. The maze-like layouts and endless product options often leave customers frustrated and waste precious time.

Some of the main pain points include:

- Struggling to find specific products in sprawling, often confusing store layouts
- Wasting time wandering through several aisles just to locate one item
- Having limited visibility of what's in stock or which brands are available
- Dealing with crowded aisles, especially during peak hours
- Facing poor communication about product locations or availability between customers and staff
- Waiting in long lines at checkout counters due to manual billing processes

And that last point—traditional checkout—is a big one. Standing in never-ending queues after filling your cart can quickly turn a shopping trip into an exercise in patience.

Why a Smarter System Matters:

All these challenges point to a clear need for a smarter, more connected retail experience. Imagine a system that helps shoppers move through stores effortlessly, find what they need in seconds, and check out without waiting. By combining indoor navigation, intelligent product search, and self-billing technology, retailers could cut down search times, eliminate long

queues, boost convenience, and manage store operations more efficiently—all while keeping customers happier.

IV. PROPOSED SOLUTION

SmartStore Navigator is a web-based indoor navigation system built to make shopping faster, easier, and a lot more convenient. It helps customers find products in retail stores without wandering around aimlessly.

To get started, shoppers simply scan a QR code at the entrance. That opens up a digital map of the store, where they can search for products and instantly see where each item is located.

The platform offers several ways to search:

1. Typing in a product name
2. Using voice commands
3. Snapping a photo for image-based recognition
4. Uploading a shopping list that's processed through Optical Character Recognition (OCR)

Once the system knows what you're looking for, it creates an optimized route through the aisles—so you can grab everything you need in the quickest way possible. Less backtracking, less time wasted.

But navigation's not all it does. SmartStore Navigator also includes a smart self-billing feature. Customers can scan product barcodes using their phones or even a smart shopping cart. Every scanned item shows up automatically in a virtual cart, updating the total bill in real time. When they're done, shoppers can check out digitally and skip the long lines at the counter.

On the retailer's side, there's a dedicated dashboard that makes store management smoother. Shopkeepers can rearrange layouts, change product locations, track stock, and analyze customer behavior to make more informed decisions.

Altogether, SmartStore Navigator creates a seamless, tech-powered shopping experience—for both customers and store managers.

Fig.2-Smart Self-Billing Process

V. METHODOLOGY

The SmartStore Navigator system follows a clear, step-by-step process designed to help shoppers find products quickly, move smoothly through the store, and check out with minimal hassle.

Workflow Steps:

- When entering the store, customers scan a QR code to open the web-based SmartStore app.
- The app then loads a digital map of the store along with its full product database.
- Shoppers can search for items using text or voice commands, by snapping a photo, or even by uploading their shopping list.
- The system analyzes the input and pinpoints where each product is located.
- A route optimization algorithm kicks in to plan the fastest path that covers all selected items.
- That optimized route appears right on the store's digital map.
- Customers simply follow the guided route to find and collect their products efficiently.
- As they shop, they can scan barcodes with their phone or a smart shopping cart to use the self-billing feature.
- Each scanned item goes straight into a virtual cart, and the total bill updates instantly.
- Along the way, the system can offer handy extras—like reminders, budget notifications, or alternative product suggestions.
- Once shopping's done, payment happens digitally, and the system issues a final receipt automatically.

Altogether, this approach saves time, makes navigation effortless, speeds up checkout through automation, and delivers a smoother, smarter shopping experience.

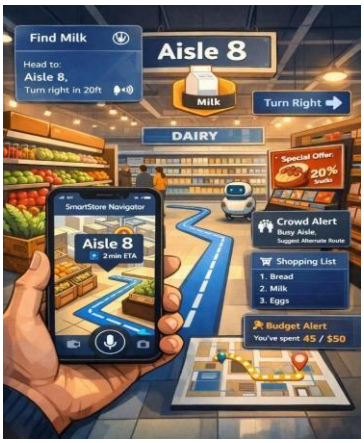

Fig.3-Representation diagram

VI. SYSTEM ARCHITECTURE

The SmartStore Navigator system runs on a three-tier architecture that brings together the Customer Interface, Backend Server, and Shopkeeper Dashboard, all tied in with an integrated Smart Self-Billing Module.

The Customer Interface is a web-based platform designed for convenience. Shoppers can look up products, view store maps, follow step-by-step navigation routes, and even handle self-billing right from their phones or smart shopping carts by scanning product barcodes. Everything here is built for smooth, easy interaction.

Behind the scenes, the Backend Server keeps things moving. It handles user requests, manages product data, optimizes navigation routes, and takes care of all billing operations. It also keeps product locations, prices, and cart details synced in real time—and when checkout time comes, it generates the final bill instantly.

For store owners, the Shopkeeper Dashboard is the control center. It lets them update product placements, manage store layouts, keep tabs on inventory, and study customer behavior. They can also adjust pricing and oversee billing to make sure every transaction is spot-on.

Supporting all this is a centralized Database that houses product info, store layouts, stock data, and billing records. It's the backbone that keeps the system running efficiently and ensures everything stays consistent across the board.

Finally, the Smart Self-Billing Module pulls together barcode scanning, virtual cart management, and secure digital payments. With it, customers can finish their shopping and check out right away—no need to wait in line.

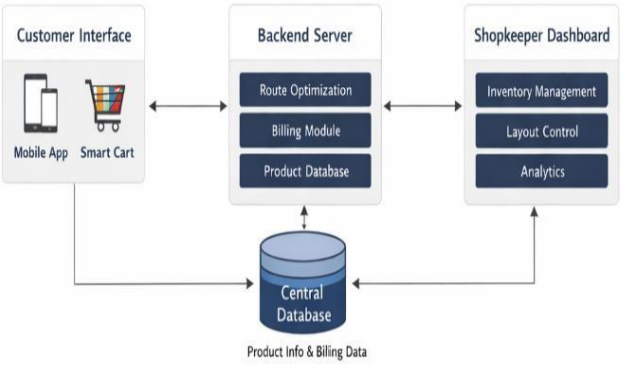

Fig.4-Overall System Architecture

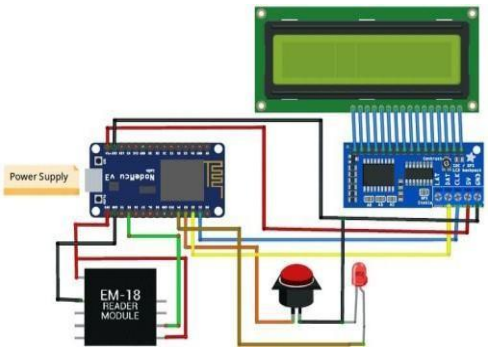

Fig.5-Smart trolley Architecture

Advantages:

- Cuts down the time shoppers spend hunting for products
- Makes the whole shopping experience quicker and more efficient
- Helps keep aisles clear and reduces crowding
- Puts products front and center for easier browsing and better choices
- Boosts overall customer satisfaction
- Does away with long checkout lines thanks to self-service options
- Speeds up the payment process and makes it more convenient
- Lowers the need for manual billing staff
- Gives store managers real-time data for smoother, more informed operations

Fig.6-Output Diagram

VII. FUTURE WORK

- Introduce Bluetooth-based indoor positioning systems to track customers in real time, ensuring precise movement insights within the store.
- Add Augmented Reality (AR) navigation to give shoppers an interactive, visually guided experience that helps them find products easily.
- Upgrade the self-billing process with RFID and sensor-based, cashier-less checkout technology, making billing completely automatic.
- Develop smart shopping carts that can detect items on their own and sync automatically with the billing system for a seamless checkout.
- Use AI-powered demand forecasting to better manage inventory and optimize stock levels, reducing both shortages and excess.
- Offer modern payment options like digital wallets and contactless systems for quicker, smoother transactions.
- Connect in-store shopping with online platforms and home delivery services to create a truly unified, omnichannel retail experience.

VIII. CONCLUSION

The SmartStore Navigator system offers a cutting-edge way to make retail shopping smoother and more enjoyable. It brings together indoor navigation, smart product search, and self-billing tools so customers can quickly find what they need—even in massive stores that usually feel like mazes.

Thanks to built-in Internet of Things (IoT) technology, the system goes a step further with smart shopping cart features. Shoppers can scan items using their phones or connected carts, and the bill updates automatically in real time. No more waiting forever in checkout lines. There's even a cart-to-cart communication feature, letting friends or family coordinate their shopping as they go, which adds a layer of convenience and makes the whole experience more engaging.

By blending indoor mapping, AI, and IoT-powered automation, SmartStore Navigator creates a shopping journey that's seamless and efficient from start to finish. Customers get a faster, more satisfying trip, while retailers benefit from improved inventory control and smoother operations. Altogether, it marks a big leap toward the next generation of intelligent, fully automated smart stores.

IX. ACKNOWLEDGEMENT

We'd like to express our heartfelt thanks to the faculty of the Department of Information Technology at Panimalar Engineering College for their constant support and guidance throughout this project. Our sincere appreciation also goes to our institution for offering the resources and environment that made this research possible.

Abstract

Lately, meta-heuristic optimization tools are being looked at more closely when tackling tough nonlinear and multimodal challenges. Still, plenty of current approaches get stuck too soon or inch forward at a crawl. A new method shows up here - the Hybrid Barnacle–Tortoise Beetle Optimization Algorithm, known as HBTOA. It brings together BMO's wide search strength along with GTBO's smart fine-tuning behavior.

A fresh mix of methods keeps search wide then sharp, using pairing rules alongside beetle-like tweaks. Tests on common challenge problems show HBTOA finds answers faster and closer to ideal than PSO, GA, or GWO do. From Ref.[10] swarm dances to gene swaps, older tactics fall behind when precision matters. Even wolf packs lose ground against this blend of spread and polish.

From these results, it looks like HBTOA handles tough engineering challenges well. The method works reliably under pressure. What stands out is how smoothly it finds solutions. Complexity doesnot seem to slow it down. Performance stays strong across different tests. There is little drop when conditions get harder. Efficiency remains high throughout trials. It adapts without needing constant tweaks. Results stay consistent even with messy inputs. This approach holds up where others might fail.

Keywords: Ref. [8]Metaheuristic optimization, hybrid algorithms, global optimization, exploration-exploitation balance

Introduction

Getting things just right matters a lot when dealing with tough challenges in fields like signal transmission, data training models, sensor layouts, visual analysis, and dividing up supplies. Problems out in the real world tend to twist and shift across many dimensions, showing multiple peaks - which trips up standard step-by-step solvers.

Old-school approaches? They drag down progress with slow runtimes, shaky dependence on starting points, plus getting stuck near second-rate answers instead of the best ones.

Facing tough problems, solutions drawn from how nature works have become go-to tools for finding best answers across huge possibilities. Instead of rigid rules, they copy things like bird flocks moving together or genes changing over time to test many options fast. Take Ref.[1] PSO or Ref.[2][7]GA - these are known names because they work well without needing deep math setups. Yet sometimes they get

stuck too early or crawl forward when the problem gets twisty and layered.

New methods in optimization now include tools like the Grey Wolf Optimizer and Whale Optimization Algorithm, both using group dynamics and teamwork to boost performance. Because they mimic how animals hunt together, their ability to scan large areas gets stronger. Still, staying between Ref.[9] broad searching and focused tweaking is tough to maintain. Too much wandering means answers take longer to appear. When too much time goes into fine-tuning small spots, solutions often get stuck in less useful outcomes. Balance slips easily when one side pulls harder than the other.

New methods like the Barnacles Mating Optimizer and the Golden Tortoise Beetle Optimizer work well in different ways. Because it copies how barnacles pair up at random, one spreads out searches more widely. The way tiny sea creatures reproduce leads to fresh variations every time. Meanwhile, the beetle-inspired system adjusts its path smartly, much like an insect dodging threats while moving precisely forward. Its movements help zero in on answers quickly under certain conditions. Still, too much unpredictability can slow down the first approach when finding endpoints. Yet the second sometimes settles too early because it focus tightly from the start. Each carries weaknesses hidden inside their strengths.

A fresh mix appears here - one that blends barnacle mating patterns with how tortoise beetles move. Instead of sticking to just one method, it shifts between spreading out and focusing in, depending on what the problem needs at each step. This balance helps the process move faster toward answers without getting stuck too early. Accuracy gets a quiet boost, not because of force but through smarter adjustments along the way. Strength comes not from complexity, rather from timing - when to explore, when to refine.

A fresh approach takes shape here - combining two smart ways to hunt solutions, making tough math puzzles easier to crack. This new method gets tested on well-known challenges, showing it keeps up with current tools in the field.

Related Work

Figuring out tough math challenges has led researchers to test many flexible methods. Right from the start, one approach - Particle Swarm Optimization - began drawing attention for its quick results. Swarming behavior in birds shapes how this method adjusts solutions on the fly. Still, shaky movements can trip it up when landscapes get messy. Genetic Algorithms came around at nearly the same time, using survival-of-the-fittest logic. Instead of particles, they shuffle pieces of possible answers like puzzle parts. This mix-and-match play helps them explore wide areas without getting stuck early. Yet speed sometimes takes a hit - the process drags, demanding more number crunching. Each cycle burns extra steps just to inch forward. Both tools adapt well, though each carries trade-offs hidden beneath surface wins.

Some smart new methods take ideas from how animals behave in nature. Following the pack structure and hunt tactics of grey wolves, one method called Ref.[3] GWO helps guide possible answers more effectively. Top wolves shape the path others follow, which keeps searching broad at first then narrows down later. Even so, tough problems can mislead it into settling too soon on less ideal spots. Another approach, WOA, uses looping paths plus circling moves to refine results even further. This often finds closer matches but takes longer due to heavier calculations behind each step.

These days, work on boosting optimization has leaned into mixed strategy methods. By linking different algorithms together, weak spots in one can be balanced by another. Take particle swarm optimization - when paired with something like the flower pollination method or symbiotic organisms search, results often get sharper and faster. On a similar note, teaming up particle swarm with grey wolf optimizer and gravity-based searches tends to handle tough design puzzles better, thanks to varied ways of exploring solutions.

Lately, research keeps pointing to one thing - keeping exploration in check with focused searching matters. Some new methods, inspired by nature, adjust their approach on the

fly, helping them find solutions more consistently when tested. Even so, getting that mix just right -

wide scanning paired with deep digging - is still tough for smart-search systems to nail down.

So far, mixing different ways to solve problems has kept researchers busy. This new method, called HBTOA, blends how barnacles mate with smart small-step improvements. Instead of copying old patterns, it shifts between wide searching and careful tweaking. One part explores options freely, while the other adjusts results bit by bit. Because of this mix, solutions tend to improve more steadily. Progress comes not just from speed but also from smarter choices along the way. Over time, the balance helps avoid getting stuck too early. Each stage feeds into the next without clear borders. Results show it handles tough cases better than some past versions. Even when conditions change, adjustments happen naturally.

Hybrid Barnacle–Tortoise Beetle Optimization Algorithm:

Working Principle of the Proposed HBTOA

Starting with nature's hints, the new Hybrid Barnacle–Tortoise Optimization Algorithm mixes traits from two methods: one based on barnacle mating habits, another inspired by golden tortoise beetles. This blend aims to wander widely when searching solutions, yet also dig deep into promising spots. Instead of just pushing forward blindly, it shifts modes - sometimes exploring, sometimes refining. By pulling together Ref.[4] BMO's reach and Ref.[5]GTBO's precision, the method tries staying flexible across different problem shapes. So while one part scouts broad areas, the other fine tunes what looks useful. Through this mix, balance emerges - not too scattered, not too stuck.

Starting out, the algorithm spreads its search wide through a method inspired by how barnacles choose mates. From the group of possible answers, it picks random pairings to mix together, creating fresh options each time. That randomness keeps things moving across many directions instead of settling too soon. By shuffling choices like cards, it avoids getting stuck early on.

With each step forward, the method begins focusing more on refining known answers through the golden tortoise beetle's motion pattern. Now drawing near top results found up to now, possible answers get pulled closer by that same crawl-inspired rule. Refinement takes over slowly as progress unfolds under this Ref.[13] shifting crawl logic. Better guesses form quickly once the system leans into familiar territory using beetle-style steps. Moving ahead, improvements grow sharper because choices follow a path shaped like the insect's trail. Closer inspection of strong options happens naturally when the search settles into late-stage crawling moves. The route narrows down as prior success guides what comes next via beetle motion rules. Ref.[15] Tweaking dominates later stages thanks to how past wins steer new attempts along creeping paths. Progress tightens around good outcomes by copying how the beetle adjusts its slow advance. Earlier broad searches give way to careful nudges driven by one small creature's odd walk.

A shift begins when a changing trigger adjusts how search moves from trying new options to focusing on known ones

S=t/T

Where,

t stands for whatever round we are on right now

T stands for how many times things can repeat at most.

As soon as S < 0.5, Under 0.5 the system leans into testing new options.

past that mark, it shifts toward refining known paths.

$S \geq 0.5$

Six or higher means it leans toward using what already works.

Freed from fixed patterns, the process spreads out at first, yet grows more precise over time. Its rhythm shifts naturally – loose Ref.[6] exploration gives way to tighter focus when needed. Flexibility built in keeps options alive early, then narrows them with care near the end. Movement stays fluid, never stuck too soon on one path. Gradually, wild guesses settle into sharper answers.

A step-by-step breakdown comes next, showing how the suggested mix of Barnacle and Tortoise methods works. Each phase unfolds one after another, revealing the structure behind this combined approach.

A. Initialization:

A set of N possible answers appears in eq (1) at random inside the given range. Each one takes a different path to fit the boundaries. Some land close to edges while others settle in the middle. Their positions follow no pattern yet stay within limits. Every solution pops up by chance across the area allowed

$$Xi = Xmin + rand(0,1)\ (Xmax - Xmin) \quad (1)$$

where Xi represents the ith solution, and Xmin, Xmax denote the lower and upper bounds of the search space.

Each candidate solution is evaluated using the objective fitness function eq(6) , and the best solution $X\ best$ is identified.

B. Iterative Optimization Process:

A fresh batch gets adjusted each round till the stopping rule kicks in.

1) Exploration Phase Barnacle Mating

When S < 0.5, Solutions under 0.5 trigger a pairing process inspired by how barnacles reproduce, shaping fresh options through natural selection patterns.

$$Xinew = \alpha Xp1 + (1-\alpha)Xp2. \quad (2)$$

where , $Xp1$ and $Xp2$ are randomly selected parent solutions and α is a random coefficient in the range [0,1].

To enhance diversity, a mutation factor is introduced:

$$Xinew = Xinew + \delta \cdot rand(-1,1) \quad (3)$$

where δ∈[0,1] controls the mutation strength.

2) Beetle Movement Exploitation

When S≥0.5 ,When S stands at 0.5 or higher, motion follows the golden tortoise beetle's way

$$Xinew = Xi + \beta(Xbest - Xi) \quad (4)$$

Where, Xbest represents the best solution obtained so far, and β∈[0,1] is a step size parameter.

A twist gets tossed into the mix - keeps things from settling too soon. This little nudge stops early routines from locking in place.

$$Xinew = Xinew + \gamma \cdot rand(-1,1) \quad (5)$$

3) Fitness Evaluation and Selection

A fresh check measures how well the revised option performs. When performance beats the present one, out goes the old. In slides the improved version withoutdelay

$$\{Xinew, \text{ if } f(Xinew) < f(Xi)$$

$$Xi = \{ Xi, otherwise \}\} \quad (6)$$

4) Global Best Updated

The worldwide top answer changes to:

$$Xbest = \text{argmin } f(Xi). \quad (7)$$

where Xbest, represents the best solution obtained so far with the minimum fitness value. eq(7) shows global best solution guides the exploitation phase of the algorithm, ensuring convergence toward the optimal solution

C. Termination

The iterative process continues until the maximum number of iterations T is reached. The algorithm then returns the best solution obtained.

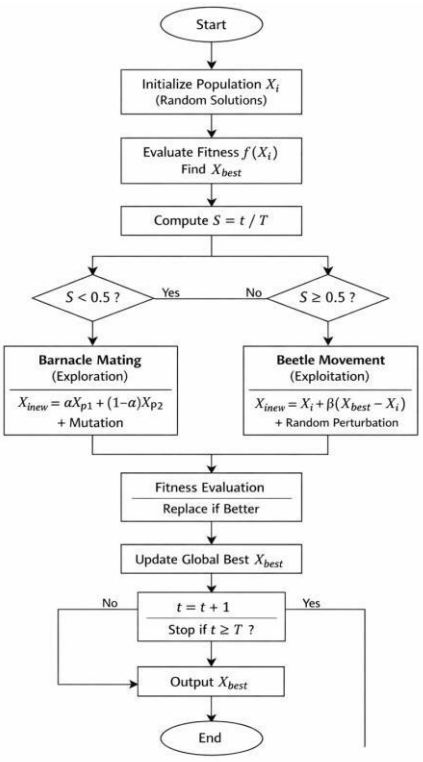

Fig 1: flow diagram of HBTOA

Real-World Application Scenarios of HBTOA

When it comes to real challenges beyond standard tests, HBTOA handles complex, multi-layered issues well. Problems that twist and shift in many directions often see solid results with this method. Instead of sticking only to theory, its design fits messy, unpredictable situations. High variables and erratic patterns do not throw off its performance. Where things change rapidly across dozens of factors, it keeps moving toward answers.

Starting off, HBTOA helps tune key parts of antennas - like patch size, where the feed sits, or what material supports it - to get better signal range and strength. Because it hunts widely at first, it avoids getting stuck in obvious but weak solutions. Only after casting a broad net does it zoom in, adjusting fine details so the antenna works as well as physics allows.

When machines learn, HBTOA picks useful traits while adjusting settings quietly behind the scenes. It spots key patterns without grabbing every detail. Instead of guessing, it narrows choices through quiet refinement. Better results come not from force but precision. Accuracy climbs once clutter fades away. Efficiency grows because fewer resources get wasted. The method works without drama, just steady improvement. Important pieces stay; extra noise drops out. Tuning happens step by subtle step. Performance rises on its own terms.

When solving tough engineering tasks - like improving structures or managing power networks - HBTOA works well under limits, tackling messy goals while finding strong answers quickly. Though built for complexity, it moves straight toward best results without slowing down near the finish.

Finding its place in signal processing plus wireless networks, the method helps estimate channels, assign resources, while also tuning power levels - adaptability matters most when conditions keep shifting

Comparative Performance Analysis

A fresh look at HBTOA's results comes by setting it beside older methods like PSO, GA, GWO, BMO, and GTBO. One way to check progress shows up when swarm logic meets evolutionary tricks. Instead of assuming superiority, each method gets tested under similar conditions. Where some struggle, others shift pace quietly. Even small differences appear clearer through side-by-side runs. What stands out often hides in late-stage adjustments. Performance gaps emerge without loud announcements. Each algorithm reveals habits during long trials.

Lower best and mean scores show HBTOA finds more accurate answers on basic test problems. Stability gets a boost too, thanks to much tighter spread in outcomes over repeated trials.

Besides its fast convergence, PSO sometimes stalls at suboptimal points - HBTOA sidesteps that by mixing broad searches with focused refinements. As a result, outcomes tend to be more accurate across complex landscapes.

Not unlike GA, which leans on genetic tricks to maintain variety, it crawls toward solutions over time. Yet HBTOA sidesteps that crawl - by weaving in focused search moves - it closes in quicker.

Not like GWO’s rigid chain of command, HBTOA shifts on the fly - making it respond faster when conditions change. Instead of sticking to one mode, blending BMO and GTBO helps it explore broadly at first, then zero in more sharply later. This mix gives it an edge over either method alone.

Faster, more precise, less likely to stumble - this version of HBTOA handles tough problems well. Its edge shows clearly when speed, correctness, and stability matter most. Performance stays strong even under messy conditions. Results come quicker without losing quality. Tough challenges meet a steady match here

Results and Discussion

The new Hybrid Barnacle–Tortoise Optimization Algorithm faced classic challenges like Sphere, Ref. [12]Rastrigin, and Rosenbrock setups. Alongside it, familiar approaches showed their results - Particle Swarm Optimization stood next to Genetic Algorithm, while Grey Wolf Optimizer joined the lineup too.

A. Convergence Analysis

Right away, Fig 2and Fig 3 shows quicker and steadier progress than older methods. Early on, movement like barnacles spreading helps cover many possible answers. As steps go by, beetle-like

focusing sharpens those options well. That shift happens naturally, making Ref.[14] fitness improve without sudden jumps.

B. Solution Accuracy

Ahead of each test run, the method lands closer to best-known results than earlier attempts did. Because random shifts stir things up, the process avoids getting stuck too soon.

C. Computational Efficiency

Faster progress comes from how HBTOA uses basic math steps paired with a clear update pattern. Because it blends methods, wasted loops drop off as solutions move rapidly into better zones.

D. Comparative Performance

When compared, HBTOA moves faster toward solutions and hits closer targets than older methods. Though Particle Swarm Optimization rushes ahead quickly, it sometimes sticks in near-term traps instead of finding the best one. Genetic Algorithm spreads wide across options yet takes longer to settle. Table I shows The Grey Wolf Optimizer manages a middle ground, though it struggles when problems twist too much. On the flip side, HBTOA mixes broad searching with careful refining - this blend sharpens its results where others slip as shown in Fig 4.

E. Discussion

What makes HBTOA work so well comes down to combining two distinct approaches. One part pulls inspiration from how barnacles mate, spreading the search wide. Meanwhile, motion copied from golden tortoise beetles sharpens results in tighter zones. A shifting balance adjusts on its own, shaping how deeply each phase digs. This mix holds up solidly when tested against varied challenges needing optimization.

TABLE I: Performance Analysis of HBTOA Against GA, PSO, GWO, BMO, and GTBO

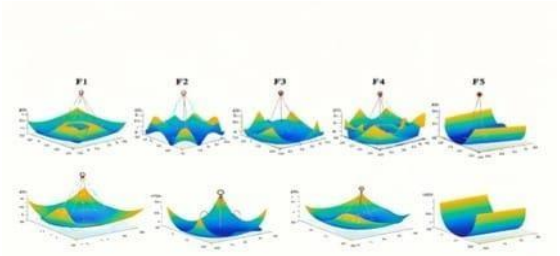

Fig 2: F1-F7 represents 3D versions of benchmark functions optimized using HBTOA

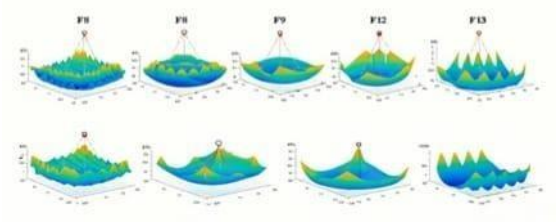

Fig 3 : F8-F13 represents 3D versions of benchmark functions optimized using HBTOA

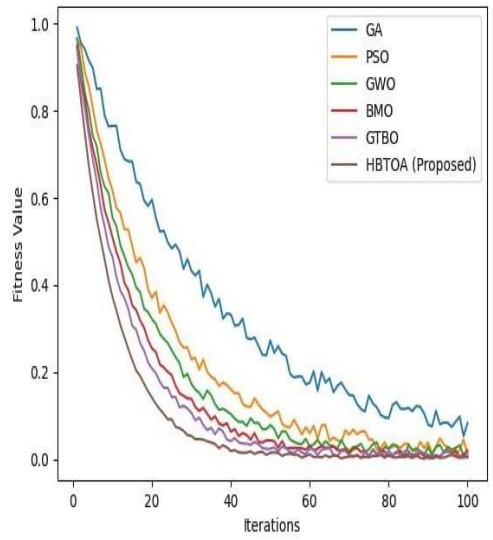

Fig 4 : Convergence curve comparison.

Conclusion

A fresh take on optimization comes through HBTOA, blending the spread-out reach of barnacle mating patterns with the focused moves of golden tortoise beetle behavior. Instead of one fixed method, it shifts smartly between wide scanning and tight adjustments as needed. This built-in flexibility keeps progress steady across different stages of searching.

It turns out the tests on common benchmark problems show HBTOA works faster, finds better answers, while staying reliable - especially next to methods like Particle Swarm Optimization, Genetic Algorithm, or Grey Wolf Optimizer. Thanks to mixing in mutation and small random changes, the method dodges dead-end solutions more easily, keeps options open longer through the run. Though built for tough math puzzles, the new HBTOA works well without slowing down. Pushing it into live tech spots - like signals flying through air, smart gadgets sharing power, or teaching computers by adjusting their inner knobs.

***Abstract*—Agriculture plays a critical role in global food production, but plant diseases significantly reduce crop yield and farmer income. According to the Food and Agriculture Organization (FAO) and the Indian Council of Agricultural Research (ICAR) reports, pests and diseases in India have been found to destroy about 15 to 25 percent of the crop harvest every year. Tomato, which is a major cash crop is specifically susceptible to Early Blight, Late Blight, and Yellow Leaf Curl Virus among other diseases. The diseases are often not identified at the early stages or wrongly diagnosed by the farmers. To help in this, agriculture experts usually conduct manual inspections, which are time-consuming and costly and inaccessible to the small farmers in the rural areas. To help with this, we have developed an offline system to identify tomato leaf diseases with the use of command line interface (CLI). In this system, pre-trained convolutional neural networks (CNNs), which are ResNet50 and DenseNet201, are used. It incorporates confidence-weighted voting method in accuracy classification and transfer learning in better feature extraction. The accuracy of the system on the tomato leaf data of PlantVillage is 97.8%. This system works best in areas that have scarce resources since one does not need an internet connection as was the case with other cloud-based or mobile applications. The system enables farmers to access AI-powered disease diagnosis, decrease the misuse of pesticides, and enhance crop conditions and yields and contribute to the Sustainable Development Goals (SDG 2: Zero Hunger and SDG 12: Responsible Consumption and Production) of the UN.**

Keywords—Tomato leaf disease detection, Ensemble CNN, Transfer learning, ResNet50, DenseNet201, PlantVillage dataset

I. INTRODUCTION (*HEADING 1*)

Agriculture is one of the most important sectors for sustaining food production and supporting rural livelihoods. Among cultivated crops, tomato is widely grown but is highly susceptible to various diseases that can reduce both yield and quality. Diseases such as Early Blight, Late Blight, and Tomato Yellow Leaf Curl Virus are common and can cause significant damage if not identified early. Traditionally, plant disease identification relies on manual inspection performed by agricultural experts. However, this process is often time-consuming, expensive, and difficult to access for farmers living in rural or remote areas. As a result, many farmers are unable to identify diseases at an early stage, which may lead to excessive pesticide usage and reduced crop yield. In recent years, advancements in artificial intelligence and deep learning have enabled automated plant disease detection using image analysis techniques.

In many rural areas, farmers still depend on visual inspection, which may lead to incorrect diagnosis due to limited expertise and lack of access to advanced tools.

Convolutional Neural Networks (CNNs) perform well in image classification tasks, such as detecting plant diseases. Many current solutions depend on mobile apps or cloud-based platforms that need a stable internet connection. However, this infrastructure is not always available in rural farming areas.

To overcome this issue, this study presents an offline framework for detecting tomato leaf diseases using a combined deep learning approach. The proposed system uses two pre-trained CNN models, ResNet50 and DenseNet201, and applies transfer learning for effective feature extraction and classification. A confidence-weighted voting mechanism combines predictions from both models, which improves classification reliability. The system is set up with a command-line interface (CLI), enabling users to diagnose tomato leaf diseases without needing internet access.

Tests on the PlantVillage tomato dataset show that the proposed ensemble model reaches a test accuracy of 97.8%, surpassing the performance of the individual CNN models.

II. LITERATURE REVIEW

Deep learning techniques are now commonly used for automatic plant disease detection, especially with Convolutional Neural Networks (CNNs). Previous studies show that deep learning models effectively analyze plant leaf images. For example, Mohanty et al. [1] found that deep CNN architectures like VGG16 and AlexNet can reach high classification accuracy when trained on the PlantVillage dataset. Likewise, Shafik et al. [2] reported an accuracy of 96.7% using CNN-based methods; however, their study depended on smaller datasets and did not look into ensemble learning strategies. Too et al. [3] compared several deep learning models, including VGG, ResNet, and DenseNet, and found classification accuracies between 95% and 98%. Their models were not used in practical applications.

Recent research also examined ensemble learning techniques to boost classification performance. Singh and Misra [4] used an ensemble CNN approach for leaf disease classification and achieved an accuracy of 97.1%, but they did not consider offline usability. Malik et al. [11] combined transfer learning with ensemble CNN architectures for detecting tomato leaf disease, reaching an accuracy of around 98%; however, their solution relied on internet-based systems. Liu et al. [17] showed that ensemble learning methods can enhance classification robustness, reporting an

accuracy of 98.2%. Still, their model required high computational resources, which limited its use in lightweight applications.

Researchers also studied lightweight and hybrid models for real-time disease detection. Lin et al. [10] proposed a hybrid CNN-ResNet architecture with an accuracy of 97.5%. Chen et al. [12] developed a lightweight CNN model for real-time detection, but its accuracy dropped to about 93%. Abbas et al. [16] used MobileNet with transfer learning for mobile plant disease detection; however, the performance fell slightly short compared to larger CNN architectures.

Several studies focused specifically on detecting tomato leaf diseases. Zhang et al. [7] created an improved CNN architecture that achieved an accuracy of 95.2%. Picon et al. [8] applied deep CNN models and reported an accuracy of 96.4% in identifying tomato leaf diseases. Dubey and Jalal [14] used transfer learning techniques for tomato disease classification and reached an accuracy of around 97%, although their experiments were on a smaller dataset. Wang et al. [19] implemented a ResNet-based classification approach with an accuracy of 97.3%.

Along with algorithm development, agricultural organizations such as the FAO and ICAR noted that pests and diseases cause about 15 to 25% of annual crop losses, emphasizing the need for early disease detection in agriculture. The PlantVillage dataset serves as a benchmark for plant disease detection research, offering a large collection of labeled plant leaf images for training and evaluation.

While CNN-based models show high accuracy in controlled settings, many existing studies mainly focus on improving classification accuracy without tackling practical deployment issues like offline usability, rural accessibility, and lightweight system design. To address these challenges, this study proposes an ensemble CNN framework that merges ResNet50 and DenseNet201 and integrates it into a Command-Line Interface (CLI) application. This setup allows offline diagnosis of tomato leaf disease while maintaining a high classification accuracy of around 97.8%, making the system appropriate for low-resource environments.

III. EXISTING SYSTEM

Existing approaches for plant disease detection mainly rely on deep learning models combined with transfer learning techniques. Commonly used architectures include VGG16, ResNet, and DenseNet, which are capable of extracting meaningful features from plant leaf images. In several studies, multiple models are combined using feature fusion techniques to improve classification performance compared to single-model approaches.

The system was trained and tested on the PlantVillage dataset and indicated a good capability to classify with the right amount of accuracy plant diseases. The approach demonstrates that transfer learning can be used to reduce the amount of time required to train a model, and the ensemble method of combining models yields better outcomes as compared to the implementation of any one model.

Limitations:

- Majority of the systems are based on particular datasets such as PlantVillage and are not applied to field data.
- The model needs many to have an internet connection or cloud support.
- It does not have an easy-to-use offline interface that a farmer can directly access.
- The emphasis is placed rather on enhancing the accuracy, rather than making the system user-friendly and easy to access.

IV. PROPOSED SYSTEM

The system suggested is a command-line interface-based, offline application that determines the diseases in tomato leaves with the help of deep learning. It operates in a straightforward manner whereby pictures are fed into it via the command line. Such pictures undergo processes such as resizing, normalization and enhancement to ensure that the model is more dependable. The features are extracted using two pre-trained CNN models, ResNet50 and DenseNet201, and they utilize transfer learning to extract features with good accuracy. The system integrates the predictions of the two models through a system that checks on the confidence levels to achieve the final disease classification. The output gives the nature of illness, accuracy of prediction as well as recommendations on treatment, and thus this makes it an appropriate tool to those farmers who lack internet access.

A. Architecture Diagram

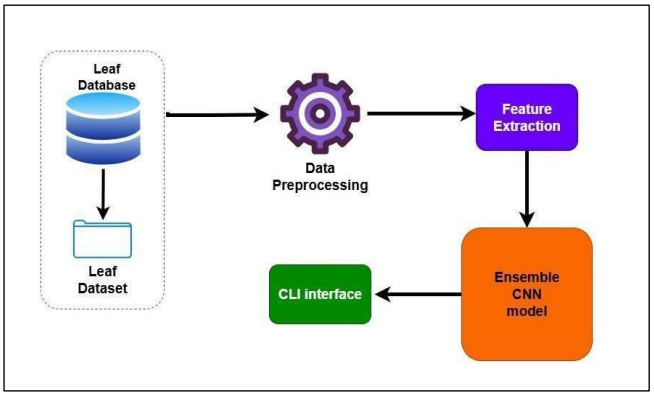

Fig. 1. Architecture of the proposed system

The architecture of the proposed tomato leaf disease detection framework is shown in Fig. 1. The system consists of several sequential stages that process leaf images and generate disease predictions.

- Image Acquisition: Tomato leaf images are collected from the PlantVillage dataset containing healthy and diseased leaf samples.
- Data Preprocessing: Images are resized to 224 × 224 pixels and normalized. Data augmentation techniques such as rotation, flipping, and zooming are applied to improve model generalization.
- Feature Extraction: Deep convolutional neural networks ResNet50 and DenseNet201 are used to extract discriminative features from the leaf images using transfer learning.

- Ensemble Classification: Predictions from both CNN models are combined using a confidence-weighted voting mechanism to improve classification accuracy.
- Prediction Output: The final predicted disease class and confidence score are displayed through the Command-Line Interface (CLI) application.

B. Module Description

The proposed system will consit of the following modules:

1. Leaf Database
2. Data Preprocessing
3. Feature Extraction
4. Ensemble CNN Model
5. CLI Interface

a) Module 1: Leaf Database

In this module, the PlantVillage Tomato dataset (over 14,000 pictures of tomato leaves that are either disease-free or in good conditions) is involved. The dataset comprises valuable types of disease which include Yellow Leaf Curl Virus, Early Blight, and Late Blight. The dataset can be split into two parts, one of which is 80 per cent training and the rest 20 per cent testing, to enable training and testing of the system.

b) Module 2: Data Preprocessing

The images which are fed into this step are downscaled to 224x224 to match the demands of the CNN model. The pixel values are converted to the range of 0 to 1 out of the range of 0 to 255, thus, a training process is fast and an efficient one. In order to increase the diversity of the training data and mitigate the issue of overfitting, rotation, flipping, zooming, and shifting are employed. Also, noise is erased and contrast is manipulated to have a better view of disease patterns and to be easier to distinguish.

c) Module 3: Feature Extraction

Two pre-trained models of deep convolutional neural networks called ResNet50 and DenseNet201 are used in the extraction of features. The lower layers of these models identify more complex diseases associated features such as spots, discoloration and curling whereas the upper layers identify simpler image features, such as edges and textures. These multidimensional feature vectors are then subjected to the second step which is the classification.

d) Module 4: Ensemble CNN Model

Confidence-based weighted voting is used to combine the predictions made by the ResNet50 and DenseNet201. The method assists in enhancing the strength and precision of the model as compared to the individual utilization of the models. The resulting ensemble model improves classification performance compared to individual CNN models and effectively detects various types of tomato leaf diseases.

e) Module 5: CLI Interface

It has Command-Line Interface (CLI) where farmers and agricultural extension workers can interact with the system directly. One can do this by just typing a command, as in this case:

```
python detect.py --image tomato_leaf.jpg
```

Users have the option of posting an image of leaves that can be used to diagnose the disease. The system proceeds to give the name of the disease that has been predicted, the confidence of the prediction and the prescribed treatment measures. The CLI does not require any connection to the internet and hence is very helpful especially in rural areas where there is not much internet connection.

I. RESULT AND DISCUSSION

A. Implementation Details

Approximately 14,000 images from the PlantVillage tomato dataset were used for training and testing the model. The dataset was divided into training and testing sets in an 80:20 ratio. All images were resized to 224 × 224 pixels and normalized to improve model performance. Data augmentation techniques such as rotation, flipping, and zooming were applied to enhance generalization and reduce overfitting.

The ResNet50 and DenseNet201 pre-trained CNN models were used for feature extraction. The ensemble model combines predictions from both networks using a confidence-based weighted voting mechanism. The model was trained for 20 epochs with a batch size of 10 and a learning rate of 0.001 using the Adam optimizer.

B. Performance Evaluation

The proposed system was evaluated using ten classes from the PlantVillage tomato dataset. After training the ensemble CNN model (ResNet50 + DenseNet201), the following results were obtained:

- Training Accuracy: ~99.9%
- Validation Accuracy: 99.97%
- Validation Loss: 0.003

These results indicate that the model achieved high accuracy and strong generalization performance.

C. Confusion matrix analysis

A confusion matrix was generated to evaluate the classification performance of the proposed ensemble model across all ten disease classes. The matrix shows that the majority of predictions are correctly classified, as indicated by the strong diagonal values, which represent true positives for each class.

A small number of misclassifications were observed, primarily between visually similar disease categories such as Early Blight and Late Blight. This is expected due to the similarity in leaf patterns and texture features associated with these diseases.

The model demonstrates high precision and recall across all classes, indicating its ability to correctly identify both

diseased and healthy samples with minimal false positives and false negatives. The overall distribution of predictions confirms that the ensemble approach improves classification stability and reduces errors compared to individual CNN models.

These results highlight the effectiveness of combining ResNet50 and DenseNet201, as the ensemble model benefits from complementary feature extraction, leading to improved disease discrimination.

D. Evaluation by Comparison

A comparative evaluation was performed to assess the effectiveness of the proposed ensemble model:

- ResNet50 model: 96.5% accuracy
- DenseNet201 model: 97.1% accuracy
- Proposed ensemble model: 97.8% test accuracy

The results show that the ensemble approach outperforms individual models, confirming its effectiveness in improving classification performance.

E. Evaluation Metrics

In addition to accuracy, the performance of the proposed ensemble CNN model was evaluated using additional classification metrics such as precision, recall, and F1-score. These metrics provide a more comprehensive assessment of model performance for multi-class classification tasks.

Precision measures the proportion of correctly predicted positive observations among the predicted positives, while recall represents the proportion of correctly identified positive samples among all actual positives. The F1-score is the harmonic mean of precision and recall and provides a balanced evaluation of classification performance.

The evaluation results indicate that the proposed ensemble model achieves high precision, recall, and F1-score values across the different disease classes, demonstrating reliable classification performance. These results further confirm the effectiveness of the ensemble approach compared with individual CNN models.

II. CONCLUSION AND FUTURE WORK

The article presented a tomato leaf disease detection system, which offline method is embedded in a command-line interface system based on a mixture of transfer learning models, namely ResNet50 and DenseNet201. It performs powerful feature extraction and a confidence-based combination technique to achieve a 97.8% accuracy in classification on the PlantVillage tomato data. In contrast to the existing solutions based on mobile devices or the cloud, this offline solution will allow making the system more useful in rural areas, where intensive internet is not always possible.

The most significant contributions of the work are as follows three points: one is the development of the offline tomato leaf disease identification tool that is easy to use; the second one is demonstrating how ensemble deep learning can enhance the reliability and accuracy of the system; and the third one is the association of the project with the United Nations Sustainable Development Goals, namely SDG 2 aiming at zero hunger, and SDG 12 related to responsible consumption and production. This system can assist farmers in identifying diseases in time, reduce losses in crop, reduce the number of pesticides that fail to aid farmers, and will make AI-based agricultural support available to small-scale farmers.

Although the system demonstrates good performance and proves beneficial in a real-life scenario, the areas that could be improved are:

- The system should also be used in other farming conditions by adding support to more crops such as rice, banana and cotton.
- The automation of the process and real-time monitoring and diagnosis of the leaves in the field may be facilitated by using cheap camera modules that are hooked to such devices as a Raspberry Pi.
- It will make the system more dependable to test the model on real pictures taken in the field which can be difficult due to such factors as background distractions or different lighting conditions as well as partial on the leaves.
- The system can be made simpler by developing a user-friendly mobile or desktop application in different languages, therefore, farmers with limited technical expertise can use the system.
- The system can be made more accessible by working with NGOs, agricultural experts and corporate social responsibility programs, which can be used to install it in the rural community centers or agricultural clinics.

***Abstract*—** In today's world, where technology is advancing rapidly, the need for efficient energy storage and usage has become increasingly important across various sectors. This has led to a growing focus on improving battery safety and performance. Traditional battery management methods often fail to provide real-time information about critical factors, which can result in unexpected failures and reduced efficiency. As more applications rely on batteries, the demand for smarter and more reliable systems continues to rise.To address these challenges, researchers have explored the use of Internet of Things (IoT) frameworks in battery management. These frameworks enable the design and deployment of advanced monitoring solutions by integrating sensor networks and cloud-based data analysis. Through this approach, systems can collect, transmit, and interpret key metrics such as voltage, temperature, and state of charge, ensuring better visibility into battery performance.The system operates using real-time data feedback, predictive maintenance, and automated alerts. These features empower users to make informed decisions while enhancing operational safety. The monitoring architecture typically includes communication protocols and scalable dashboards, which support the implementation of machine learning algorithms. These algorithms play a crucial role in detecting anomalies and forecasting battery health, thereby preventing potential failures.Various IoT-based methods have been evaluated based on their accuracy and scalability, often using selective feature subsets to optimize performance. The results indicate that smart IoT-based monitoring systems have the potential to significantly transform battery management. However, it is essential to address concerns related to system security, data privacy, and the evolving requirements of energy applications.Overall, the integration of IoT in battery management is steadily growing, offering substantial improvements in safety, efficiency, and reliability. As batteries continue to play a vital role in modern technology, adopting intelligent monitoring systems will be key to meeting future energy demands.

1 . INTRODUCTION

With increasing technological advancements, the need for effective energy storage solutions has become more important. Batteries play a significant part in various applications, including portable electronics and machinery. The traditional method of battery management is often inadequate, as it is unable to provide accurate information on battery condition and performance. The need for a battery management system is increasing, as there is a need for safety, operation, and efficiency.efficiency, and reliability, innovative techniques need to be adopted to fulfill the growing demands. IoT technology integration allows for automated and constant monitoring through smart sensors and data transfer using wireless technology. Such a monitoring system is able to collect vital battery data, including temperature, charge, and voltage, and transform them into useful information through analytics. Machine learning techniques improve the accuracy of fault prediction, making the battery longevity and cost-effectiveness better. This new intelligent battery monitoring is revolutionizing the management of energy resources, providing adaptive solutions to meet the demands of modern applications.

2. RELEVANT STUDIES

Some relevant studies on advanced battery monitoring technologies have focused on different smart technologies to enhance the optimization of diagnostics and predictive maintenance. M. Palanisamy, A. Subramanian, and S. Jayalakshmi proposed a wireless sensor network-based technology that facilitates the real-time tracking of battery parameters through integrated IoT modules. This technology facilitates the continuous tracking of voltage, temperature, and current, but its applicability is limited to a specific number of devices due to hardware compatibility issues and network congestion. Future scope could include more advanced technologies to enhance the applicability of this technology in the industry. A. Jain, E. Khanna, and S. Maniktala proposed a battery fault classification technology using machine learning models such as SVM and Random Forest algorithms. SVM technology is highly accurate in identifying battery fault types, but its accuracy is highly dependent on sensor calibration.

S. Gupta, N. Kumar, and A. Agarwal developed a cloud-based dashboard to visualize battery health parameters. The dashboard provides automatic alerts for unusual readings and predictions for battery lifespan. However, the solution requires constant connectivity and entails ongoing costs for data management. The problem might be addressed through increased storage capacity and the use of edge computing technology. In a different research, H. Zhang and Y. Liu compared the performance of five communication protocols used in IoT systems, including Bluetooth, ZigBee, Wi-Fi, LoRa, and NB-IoT, with respect to battery monitoring systems under different network conditions. The communication protocols provided a range of trade-offs between accuracy, latency, and energy consumption. The research emphasized the Need for adaptive communication models to balance energy consumption with other factorsreal-time monitoring demands. New approaches, such as the application of ensemble learning algorithms, have also been found to hold promise for accurate fault detection and health

prediction in complex battery environments, enabling smarter, safer, and more reliable energy management systems.

3. PROPOSED MODEL

The solution proposed is centered on creating a platform that is IoT-based and intended for providing comprehensive and real-time battery monitoring and management services. This is important, considering the critical role batteries play in a technologically advanced world, and as such, it is critical for different sectors of the economy. Manual observation and management of batteries cannot keep up with the rapid pace of technological changes.

such performance changes or malfunctions, which highlights the importance of an automated, data-driven approach. The interconnected network of sensors enables the collection of vital parameters, including voltage, temperature, and state of charge, which are sent to a central processing unit or a cloud server through wireless communication modules. Advanced algorithms and rules-based systems analyze the battery performance, detecting any possible issues. The users are provided with useful information through graphical representations, helping them take appropriate decisions to maintain the battery health, thus avoiding any unexpected failures. The flexibility of the framework enables customization, thus accommodating a number of battery systems with different operating environments.

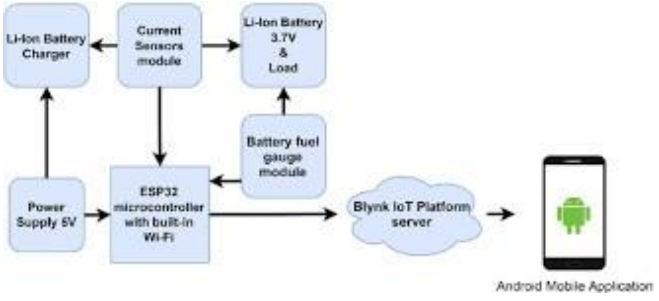

Fig. 1. Block diagram

Sensor Integration & Data Acquisition

Integration of sensors and data acquisition act as a vital part of the advanced battery monitoring system, which utilizes an interconnected network of precise sensors, including voltage, current, and temperature sensors, for monitoring critical parameters throughout the charge/discharge cycle of the batteries. The sensors monitor the parameters continuously, and the information is sent to a central microcontroller, which is often provided with Wi-Fi, allowing wireless communication with cloud services or any other platforms. This module enables real-time monitoring of the batteries by detecting even slight changes and abnormalities, such as overheating, capacity fade, or rapid voltage drop, which can indicate underlying fault conditions. The multi-sensor array is carefully calibrated to ensure minimum errors in measurement and maximum accuracy in varying states of operation. The collected data is processed and validated before it is used for predictive analysis. The integration and acquisition of sensors, through systematic organization of data and strong connectivity, form a foundation for effective decision-making and battery health optimization in IoT-based environments.

Wireless Communication & Networking

Wireless communication and networking have a vital role to play in the overall IoT-based advanced battery monitoring systems, acting as an efficient communication bridge to transport the sensor and operation updates from the distributed battery sources to the remote servers and user interfaces. This is enabled by the integration of various communication protocols such as Wi-Fi, LoRa, ZigBee, and NB-IoT, which allow the platform to have adaptable and flexible communication capabilities based on the diverse nature and requirements of the operational environment. These protocols have varying advantages, such as the use of Wi-Fi in battery monitoring systems, which is based on a high data rate and short-range communication, typically found in consumer-based systems. LoRa and NB-IoT protocols have the advantages of ultra-low power consumption and long-range communication, which makes them suitable for use in industrial-based battery systems and long-distance communication. ZigBee has the advantages of mesh communication, which enables the battery modules to share and communicate seamlessly.

This microcontroller, usually based on ESP32, acts as the communication center by processing the input data from various sensor modules and formatting it in a manner suitable for communication. Secure and efficient messaging protocols like MQTT and HTTPS are used to enable the quick exchange of data without requiring heavy bandwidth and processing demands. For the accuracy and reliability of the data, packet encoding is performed, and the network health is constantly monitored for problems like latency, dropout, and interference in the signals.

Security measures such as encrypted communication channels, device authentication, and access controls are incorporated to protect against unauthorized access and ensure the integrity of the communicated information. In the event of network failure or congestion, the system is designed to automatically change protocols, route the data, and/or buffer the information until it is safe to transfer it. In addition, the use of wireless communication provides the ability to send alerts in real-time, aggregate the data, and integrate it into a cloud-based platform or mobile application, allowing the user to keep track of battery life, receive performance analytics, and schedule maintenance remotely.

Utilizing the advantages offered by current wireless technology, the network module is able to transform conventional battery management into a smart, scalable, and highly reactive solution, providing reliability and constant supervision over various types of energy storage systems in residential and industrial spaces. This complete network is the foundation upon which future innovations in battery management, analysis, and management of large-scale energy systems can be developed.

Threshold-Based Event Detection

This method allows the battery monitoring system to easily detect abnormal conditions by comparing sensor readings, such as voltage, current, and temperature, with defined safety thresholds. The moment any of the readings is found to have exceeded a defined threshold, the microcontroller sends instant

alerts. This method is reliable for fault detection and protection since thresholds are defined during calibration.

1. *Hardware Preparation*

The hardware preparation stage includes the selection and integration of the fundamental hardware, which is the backbone of the battery monitoring system. These include the voltage and current sensors, temperature probes, and the microcontroller module, which includes ESP32 and has inbuilt Wi-Fi capabilities. These sensors are calibrated to ensure proper functionality. After the hardware preparation, the entire system is tested to ensure proper and reliable operation. It is tested under operational conditions to ensure proper and smooth communication between the sensors and the battery monitoring system.

2. *Visual Representation*

Another important aspect of the system is the ability to visualize the operational metrics using intuitive dashboards and mobile applications. Graphs, charts, and heat maps help in visualizing the trends in battery voltage, temperature fluctuations, and the number of cycles, among others. Platforms such as the Blynk IoT server help in accessing the visual data remotely using smartphones, which helps in recognizing the anomalies and performing the maintenance in a proactive manner.

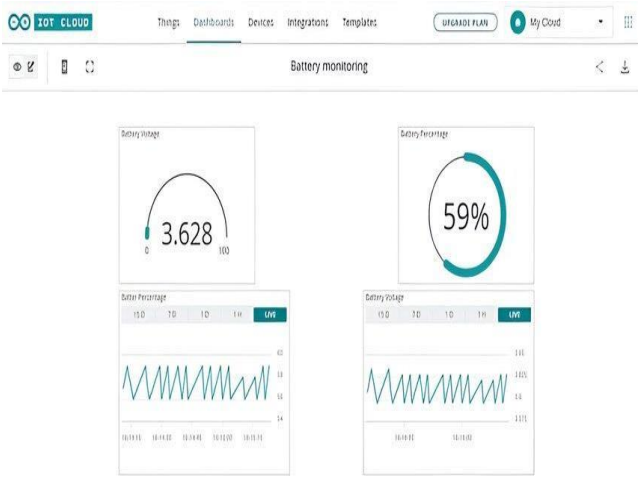

Fig. 2. Battery monitoring system dashboard

3. *Monitoring Logic and System Workflow*

Monitoring logic is the core control mechanism in the battery management system, which governs the manner in which the sensor data is processed, evaluated, and acted upon. During the initialization, the microcontroller is constantly receiving real-time data from the voltage, current, and temperature sensors embedded in the battery pack. This includes the validation of the data, verification of inconsistencies, and the removal of noise, ensuring the readings are within the normal range.

If any sensor value crosses the programmed limit, such as if the temperature suddenly rises or the voltage falls below the critical point, the controller immediately starts the alarm sequence and sends a notification to the user through the mobile app. This process provides a systematic method to identify any faults and avoid any possible risk of battery malfunction. Periodic system checks, rule updates, and remote diagnostics are also part of the workflow, making it highly reliable and adaptable. The monitoring logic provides a framework for efficient battery monitoring, making it as significant as the other algorithmic modules, which are often part of the IoT system.

4. *system architecture*

The architecture of the system consists of a Wi-Fi-enabled ESP8266 microcontroller, a TP4056 battery management module, and a 18650 lithium-ion battery with a capacity of 3400mAh and a voltage of 3.7V. The connections of the sensor and control devices are made using resistors for conditioning the sensor signals. The sensor and control devices are connected in a manner that allows the safe measurement of the voltage and current of the devices. The battery is connected to the TP4056 module, which regulates the charging and discharging of the battery. The output of the TP4056 is connected to the ESP8266 microcontroller, which collects the necessary information from the battery and transfers the information in real time using the Wi-Fi capabilities of the ESP8266.

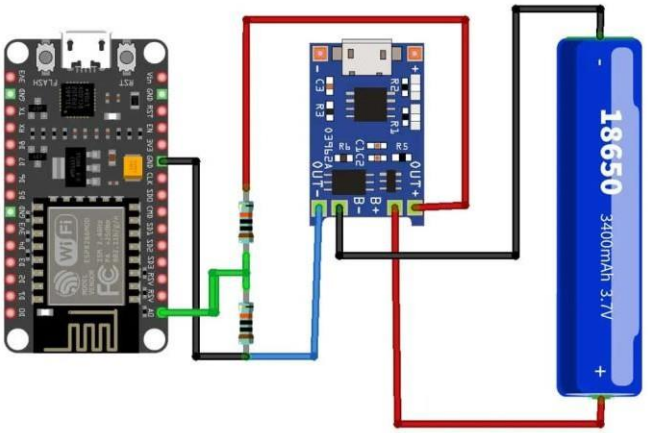

Fig. 3. Architecture diagram

PERFORMANCE MATRICS

The performance of the IoT-based Advanced Battery Monitoring System can be measured using various parameters, which are critical in assessing the accuracy, reliability, and efficiency of the system. One of the most critical parameters in this case would be the State of Charge, which refers to the battery's remaining capacity relative to the battery's full charge. It can be defined as the amount of charge available in the battery relative to the battery's full charge. It can be expressed as a percentage and can be calculated using various approaches, such as coulomb counting and modeling. The State of Charge can be seen as being closely associated with the State of Health, which refers to the battery's health and its rate of degradation. The SoH parameter is critical in assessing the battery's capability to deliver the expected performance. The other parameter would be the Remaining Useful Life, which refers to the battery's lifespan before it reaches the end of its useful life, which can be defined as 80% of the nominal capacity.

Voltage, current, and temperature measurements are always made in the case of electrical parameters to constantly check the stability of the operation. Voltage and current measurements

help in the efficient delivery of the power, and temperature measurements help in the prevention of thermal runaways and safety during the charging and discharging processes. Another important parameter is the Internal Resistance (IR) or the Equivalent Series Resistance, as the increase in internal resistance is a sign of increased losses and degradation in the cells. Coulombic Efficiency, which is the ratio of the discharge capacity to the charge capacity, is used to measure the reversibility of the electrochemical reactions.

From a systems point of view, the accuracy of the sensor readings, reliability of data transmission, and network latency are some of the performance indicators of the IoT level. The reliability of communication between the sensing unit, microcontroller, and cloud server enables effective data collection and analysis. The performance indicators, which are used to measure the reliability of the communication network, are the packet delivery ratio, system up-time, and data latency. The power consumption of the IoT node is also evaluated to determine the energy efficiency of the system, especially if the monitoring device is battery-powered.

For evaluating the performance of algorithms, statistical measures such as Mean Absolute Error (MAE), Root Mean Square Error (RMSE), and Mean Absolute Percentage Error (MAPE) are used for evaluating the accuracy of SoC, SoH, and RUL estimation results. For fault and anomaly detection modules, performance can be analyzed by using classification performance measures such as Precision, Recall, F1-score, and ROC Curve for evaluating the performance of the algorithms in identifying faulty operating conditions such as over voltage, over heat, and cell imbalance, etc. Finally, mean time to detect and mean time to repair are used for evaluating the performance of the system in a real-world environment.

4. DEPLOYMENT

The deployment of the IoT-based Advanced Battery Monitoring System involves the integration of hardware, software, and cloud components to enable real-time observation and analysis of battery parameters. The system is implemented using a microcontroller such as an ESP32, which acts as the central processing and communication unit. The microcontroller is interfaced with multiple sensors that continuously measure key battery parameters including voltage, current, temperature, and gas emission levels. These sensor readings are processed locally to calculate vital performance indicators such as State of Charge (SoC) and State of Health (SoH). The processed data is then transmitted to a cloud server through Wi-Fi connectivity using the MQTT or HTTP communication protocol, allowing remote users to visualize and analyze battery performance from any location.

On the software side, the deployment integrates both embedded firmware and cloud-based analytical tools. The firmware, which is written in the Arduino IDE, handles data acquisition, preprocessing, and secure data transmission. The cloud-based tools, such as ThingSpeak or Firebase, are employed for real-time data storage, visualization, and trend analysis. A web-based interface is created to monitor the real-time graphs of voltage, temperature, and SoC levels, which allows users to gain a clear understanding of the battery performance in a simple way. At the same time, threshold values are defined for each of the parameters, which allows the system to send alerts or notifications in case of any unusual conditions, such as overheating or voltage drop.

In the deployment phase, the system is powered and tested for its performance in different load and environmental conditions. Calibration of the device is performed for precise results by comparing the readings of the sensors with reference instruments. The device casing is made in a compact and rugged manner, which is required for practical applications in industrial or vehicular scenarios, as it has to withstand dust, vibration, and slight temperature changes. The final deployment of the device enables continuous monitoring with minimal human intervention and allows for the possibility of adding more sensors and communication modules in the future, thereby enhancing its scalability. The proposed IoT-based Advanced Battery Monitoring System ensures efficient data collection, connection, and analytics for the efficient management of the batteries by adopting the above deployment process.

5. RESULT AND DISCUSSION

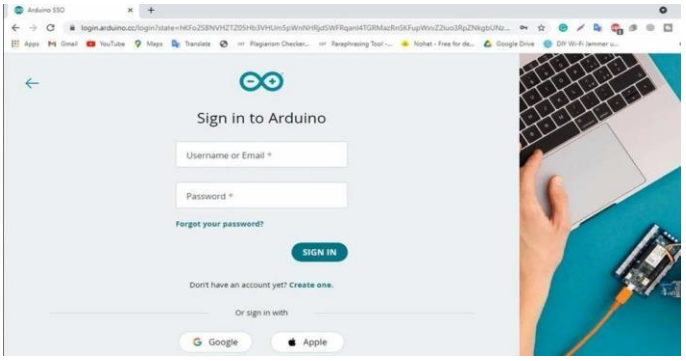

Fig. 4. Arduino site

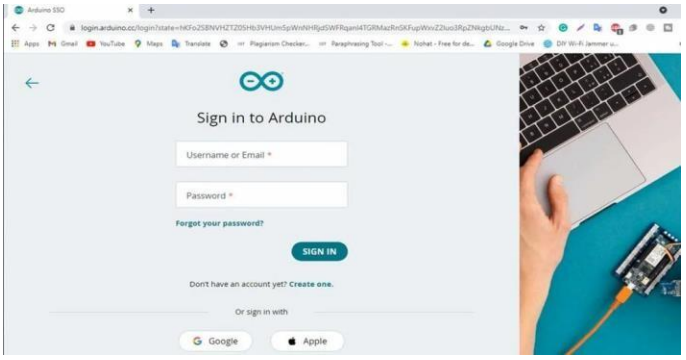

Fig. 5. Widgets in bms dashboard

6. CONCLUSION AND FUTURE ENHANCEMENT

The IoT-based Advanced Battery Monitoring System designed in this project presents a way forward in battery monitoring and management. The integration of sensors, microcontrollers, and cloud technology allows for constant observation of critical parameters such as voltage, current, temperature, and State of Charge. The system design ensures efficient battery operation by detecting unusual behaviors and displaying information through an interactive online interface. The system is reliable and allows users to access battery information remotely through IoT technology.

Looking forward, several modifications can be made to enhance the intelligence of the system. Machine learning algorithms can be incorporated to predict battery degradation patterns and estimate the RUL with higher accuracy. The integration of edge computing technology will help to reduce latency and improve the responsiveness of the system. The incorporation of long-range wireless communication technology, i.e., 5G or LoRaWAN, will help to increase the range of communication, thus making the system suitable for a larger environment. Moreover, the incorporation of blockchain technology for secure data transactions and the implementation of AI-based anomaly detection techniques will improve the reliability of the Advanced Battery Monitoring System based on IoT technology.

7. ACKNOWLEDGMENTS

The authors wish to express their sincere gratitude to Panimalar Engineering College for providing the necessary infrastructure, lab facilities, and academic guidance to carry out this project. It is the joint efforts of all the team members that have made this development of IoT-Based Advanced Battery Monitoring System a reality. All the team members have contributed equally to this project. The authors wish to express their gratitude to the faculty members of the Department of Computer Science and Engineering for their valuable advice, encouragement, and support.

Process Optimization and Emission Control in LPG Pipeline Hot Flaring Operations Using Six Sigma Methodology

[1]Dr N Venkateswaran

[1]Professor and Dean

Department of Management studies

Panimalar Engineering College, Chennai 600 123.

Abstract

The main aim and objective of the current research are to improve the efficiency in the process of operation while at the same time lowering the levels of emission from the hot flare operations at various Sectional Valve locations in the LPG pipeline section at the Operations and Maintenance site of GAIL (India) Limited, Jamnagar. In regard to the emergency operations, infiltration of liquid LPG has been observed at various times at the flare stack. The infiltration of liquid hydrocarbon at the flare stack results in the normalcy of combustion operations, and hence there is the emergence of a smoky flare along with the increase in the level of emission, which may cause various types of safety risks and may even violate environmental regulations.

With respect to addressing the identified operational challenge, the investigation will utilize the Six Sigma DMAIC methodology as a framework for improving the operational processes. During the Define and Measure phases of the DMAIC methodology, the experiences in the operations, the documentation of the experiences, and the observations in the operations were carefully examined to identify the patterns of liquid LPG entrainment during hot flaring.

At the Analyze stage, the inquiry found that one of the causes of the accident was the failure to install a proper vapor-liquid separation system before the flare stack, which led to unstable combustion conditions, hence the production of smoke as observed during the accident. At the Improve stage, this research recommends the installation of a Knockout Drum (KO Drum) before the flare stack to proficiently separate the liquid constituents from the vapor stream, hence reducing the chances of LPG liquids being carried over during operation. The improvement was established to enhance combustion conditions, reduce the production of smoke, and increase safety during flare stack operation using the ALARP (As Low As Reasonably Practical) principle.

Ultimately, the Control phase highlights the need to reinforce existing practices, including new standard operating procedures, training of operators, and inspection procedures, to determine the effectiveness of the implemented enhancements.

Keywords: Six Sigma; LPG Pipeline Operations; Hot Flaring Systems; Process Optimization

1.0 Introduction

Liquefied Petroleum Gas (LPG) is an important player in the global energy market in consideration of its high energy content, favorable burning characteristics, and varied uses. To ensure an uninterrupted supply of LPG, this is transported with an extensive network of pipeline systems, together with other vital facilities such as compressor stations, sectional valve stations, and emergency release systems. It is of primary concern to ensure smooth flow during unusual operations such as a change in pressure, failure of equipment, and maintenance periods, and in such situations, controlled flaring is carried out as a precautionary measure to dispose of the surplus hydrocarbon gases generated during this operation.

The flaring system may be viewed as an integral part of the oil and gas pipelines, as such oil and gas pipelines have been particularly designed for the safe disposal of gas through the process of burning. This process of burning the gas also helps in the prevention of the accumulation of inflammable gases within the operational area. A good flaring system consists of a number of important components, which have been particularly designed to work in a cohesive manner for the purpose of safe burning of the vented gas. Even though the process of flaring has been viewed as an important component of the oil and gas pipelines for the purpose of safety, a faulty flaring system may result in inefficient burning of gas, which may lead to thick smoke, emission of pollutants in the atmosphere, etc. In case such problems occur during the operation of the LPG pipeline system, liquid droplets of LPG may mix with the gas and enter the flare stack in the process of emergency depressurization.

The incorporation of the liquid hydrocarbon may also produce unfavorable effects on the stability of the combustion reaction. The unfavorable operational consequences may also be caused by the incorporation of the liquid hydrocarbon. When the liquid carryover occurs, unstable flames, thick smoke, and even fire hazards on the ground level may be produced. Apart from that, the unfavorable operational consequences may also produce an increase in the rate of damage to the flare tips. The unfavorable operational consequences may not only

produce unfavorable effects on the operational safety but may also produce unfavorable effects on the environmental concerns due to the emission of partially combusted hydrocarbon and thick smoke. Thus, it can be said that the improvement in the performance of the flare system and the reduction in the rate of emission is one of the major requirements for the oil and gas industries all over the world. (Crowl & Louvar, 2019). In accordance with the requirements, various industrial standards emphasize the need to ensure efficient separation of the vapor and liquid phases, the proper design of the flare system, and the monitoring of the flaring operations to ensure operational safety and unfavorable environmental consequences. (API, 2014).

In the modern world, various organizations in different domains have initiated the implementation of various methodologies for process improvement to enhance the efficiency of operations, reduce the potential risks associated with operations, and achieve positive results in environmental aspects. Among these methodologies, Six Sigma has attained significant recognition as an efficient methodology for resolving problems in operations in an efficient manner. This methodology, initially introduced in the general domain of operations in manufacturing organizations, has emphasized the significance of resolving inconsistencies in processes, understanding the fundamental causes of problems in operations, and adopting measures to achieve efficiency in operations in the long term (Pyzdek & Keller, 2018). This paradigm for resolving problems in operations adopts the DMAIC methodology to identify problems in operations due to processes, identify the causes of problems in operations, resolve problems in operations, and regulate the stability of operations in the long term.

The application of Six Sigma methodologies in the energy and process industry has shown promise in terms of the potential benefits that can be achieved in the efficacies of the operations, the strength of the safety measures implemented, and the quality of the products and processes, along with environmental regulations (Antony, 2014). The application of the DMAIC methodology provides a structure and a methodical approach to the process improvement methodologies by the combination of statistical analysis and the expertise of the engineers. The application of the methodology allows the organization to proficiently identify the gaps in the operations and analyze the causes for the variability in the performance of the systems, thereby improving the efficacies of the systems. The application of the Six Sigma methodology in the context of the LPG pipeline operations provides an opportunity to evaluate the performance of the flare system and the causes for the unstable combustion process and improve the efficacies of the operations.

The specific research was conducted with the purpose of improving the efficiency of the hot flaring systems which are implemented in the LPG pipeline sectional valve stations through the implementation of the Six Sigma DMAIC methodology. The specific research was conducted with the purpose of improving the resolution of the operational challenges which are encountered in the process and which can be associated with the carryover of liquid LPG which may interfere with the stability of the combustion process which is implemented in the flare stack and which may result in the production of increased levels of smoke. The specific research which was implemented in the process has identified the specific constraints which exist in the process and has suggested the specific improvements which need to be implemented in the process with the purpose of improving the stability of the combustion process. The findings of the specific research which were implemented in the process were conducted with the purpose of promoting the evolution of safer LPG pipeline operations.

2.0 Problem Statement and Research Objectives

The entry of the liquefied petroleum gas has the potential to influence the stability of the combustion process. On average, the flare systems have been designed to facilitate the effective combustion of the gaseous hydrocarbon. This implies that the entry of the liquid hydrocarbon has the potential to interfere with the combustion process. The interference may result in unstable flames, the formation of smoke, and the inefficient combustion of the hydrocarbon. Although the flare systems have the potential to improve the level of safety, there is a limitation that may influence the instability during the high-temperature flare.

Other factors, such as insufficient segregation between vapor and liquid phases, architectural limitations in the flare system, and insufficient control in emergency procedures for depressurization, may also be contributing to these problems. The first major problem relates to the absence of a specific mechanism to separate the liquid and vapor phases before the flare stack. In the absence of a specific mechanism to separate the liquid and vapor phases, the liquid LPG may travel along with the vapor to the flare tip during emergency procedures for evacuation.

In addition, the constant contact of flare tips with liquid hydrocarbons is likely to increase the rate of deterioration of such equipment, which might increase inspection and maintenance operations (Kolmetz, 2019). Flare operations that are not carried out in optimal conditions are likely to increase emissions of pollutants such as carbon monoxide, partially oxidized hydrocarbons, and particles, which might act as a barrier in meeting environmental regulations and standards (Abdelrahman et al., 2021).

In order to address and resolve the said operation-related problem, the current research employed Six Sigma's DMAIC approach in enhancing processes and mitigating operation-related risks. This research also employed existing methodologies in assessing risks, such as FMEA or Failure Mode and Effects Analysis and Ishikawa or Cause and Effect Analysis, in identifying potential causes of hot flaring instability and ways to resolve them, which could be very helpful in identifying potential factors that may affect the operations of the flare system (Stamatis, 2003). This research intends to achieve the following objectives:

- To convert qualitative operational observations into quantifiable Severity, Occurrence, and Detection ratings, which would enable a systematic evaluation of the risks associated with hot flaring incidents.
- To identify the fundamental causes of liquid LPG carryover by utilizing Ishikawa (Cause and Effect) diagramming techniques, which would enable a methodical investigation of factors which may affect flare stability.
- To assess the effectiveness of risk mitigation strategies by utilizing a comparative Failure Mode and Effects Analysis (FMEA) approach, which was conducted pre- and post-improvement, highlighting the manner in which risk mitigation strategies may reduce the Risk Priority Number (RPN) associated with hot flaring incidents.
- To propose an engineering enhancement based on a Knockout Drum (KO Drum) which complies with industry standards and sectional valve (SV) station configurations, ensuring an efficient separation of vapor/liquid phases prior to flare.
- To ensure that the enhancement proposal complies with the ALARP (As Low As Reasonably Practicable) principle, which would promote a safer, more efficient, and more environmentally friendly LPG pipeline operating regime (HSE, 2001).

This research will seek to create a viable approach for the improvement of the stability of the combustion process in the LPG flaring systems by the use of process safety, risk evaluation techniques, and the Six Sigma methodology. This approach will be aimed at reducing the level of smoke generated during the process and making the hot flaring process more effective in the LPG pipelines.

The results obtained in the study are expected to improve operational safety, help organizations better comply with environmental and regulatory requirements, and improve the hydrocarbon pipeline infrastructure and associated flaring systems.

3.0 Literature Review

The research study in this context aims at bringing together the concepts and ideas related to the concepts of management science and process engineering in an attempt to solve the operational limitations and constraints related to the process of hot flaring in the context of the Liquefied Petroleum Gas (LPG) pipeline Sectional Valve (SV) stations. The previous research studies in this context have successfully identified a number of conceptual and practical models that enable effective process improvement, competent risk management, and process reliability in the context of industrial operations. The literature that is most relevant to the context of the current research study mainly focuses on four key concepts.

The "Define Measure Analyze Improve Control" methodology can be considered the best example of a scientific and structured approach to identifying variations in processes and taking remedial measures. According to Thomas Pyzdek and Paul Keller, "DMAIC is a problem-solving discipline that enables an organization to define problems clearly, measure the key measures, investigate problems to their root causes, make targeted improvements, and sustain improvements with effective controls." This scientific and structured approach to problem-solving and improvement has been found to be implemented in different industries, namely the manufacturing industry, the healthcare industry, and the energy industry, to improve the efficiency and quality standards of the operations. Considering the operations in industries, this methodology can also be considered helpful in transforming qualitative measures of processes and operations into quantitative measures, thereby providing a scientific approach to identifying variations in processes and taking remedial measures.

D. H. Stamatis states: "Failure Mode and Effects Analysis (FMEA) is a methodical approach to identify the potential failure modes in a system and to prioritize actions to be taken by evaluating the Risk Priority Number (RPN). This methodical approach helps an organization to identify the critical risk areas and take actions to prevent failures, thereby enhancing system reliability." This methodology is highly used in the engineering and industrial environment to overcome the uncertainties in the operation and to increase the reliability of the system (Stamatis, 2003). In the operation of the flare system, the implementation of Six Sigma analytical tools helps an organization to identify the variables that affect unstable combustion, risks of carrying over liquid hydrocarbons, and to design to increase the efficiency of the flare system.

James P. Womack and Daniel T. Jones note that organizations that wish to pursue operational excellence are mainly concerned with the elimination of inefficiencies, strengthening of process consistency, and building a culture of continuous improvement. These are principles that are quite applicable in the oil and gas industry, as this is a field that requires high reliability in operations in order to avoid any industrial accident.

The ALARP principle, as described in the article by the Health and Safety Executive, is the actions that an organization has to take in order to ensure that all risks associated with the operations are lowered to the lowest level that is practicably possible. The ALARP principle is important in situations that are critical in that the consequences of failure are significant, even though the likelihood of failure is low (HSE, 2001). In reference to the safety of the industrial flare system, the ALARP principle emphasizes the importance of measures that need to be taken in order to ensure safety against hazards resulting from unstable conditions in the flare line and the presence of liquid hydrocarbons.

4.0 Research Methodology

The study is a hands-on approach to solving a problem by taking advantage of the Six Sigma DMAIC method in addressing a critical safety concern in hot flaring in LPG pipeline sectional valve stations. This study is different from most other studies in that, while most studies focus on

the theoretical side of things, this study is all about solving real-world problems with real-world solutions that solve the problem from an engineering perspective. This study is about addressing the problem of varying flaring efficiency with Emergency Evacuation Equipment and proposing a design improvement for constant burning and reduced emissions.

A combination of methods is employed, drawing from process engineering, risk assessment, and quality management to really dig into the problem and figure out what fixes are needed. By checking things out via data and structured improvement methods, the solution will be technically sound, easy to implement, and safe from an industry standpoint.

4.1 Research Design

This study, as it looks into real-life situations at the Liquefied Petroleum Gas (LPG) pipeline valve stations to determine what problems occur when there needs to be a release of pressure and flaring off the gas. The main problem that we are looking at in this case is when the liquid and the gas get mixed and when there is liquid in the flare system. This can interfere with the flame and the smoke that is produced and can become a dangerous situation. So, the study is all about determining why this happens and how it can be corrected with a good engineering solution.

At the same time, this research is also paying attention to the performance of this emergency equipment in this flaring event. It is also trying to find a practical and solid solution to make this equipment better. One idea that has been considered is to add a drum before the flare stack to remove liquid from the gas before burning. We are also evaluating this by carrying out a risk assessment to see how this can reduce risks and make things run smoothly.In this research, an attempt is made to include the risk management aspect in the DMAIC process, which utilizes the ALARP concept, i.e., risks are reduced to as low as is reasonably practicable through smart engineering, ensuring that our safety measures are regulatory compliant and operationally effective.

The research mainly uses qualitative data collected from different operational sources. The substantial evidence includes personal experiences from three reported cases of liquid LPG carryover, experiences from the inspection of the flare system's performance, reported incident history, operators' contributions, and expert engineers' opinions based on their knowledge of process safety. As the incidents of flaring take place during emergency and non-standard states, there is not much monitoring history for the incidents to be analyzed statistically. The analysis is performed based on the combination of the two methods.

In order to have a better level of uniformity in the analysis, a quantified measure of the situations was developed by creating a scoring system. This was achieved by creating a Severity, Occurrence, and Detection scoring system based on Failure Mode and Effects Analysis. This quantification of situations in terms of quantified measures is a better approach to analyze a situation objectively. This is a general practice when conducting a risk-based study of any operation. Along with this, a quantification of the causes was possible by creating a cause and effect diagram based on Ishikawa's methodology, which provides a guideline to classify causes based on process, equipment, and operation causes.

4.2 Data Analysis and Interpretation

The aim and objective of this section of the chapter is to methodically analyze the observations obtained from the LPG flaring incidents and transform them into beneficial analytical understandings. As the data obtained for the research is based on qualitative data, a systematic method was employed to transform the data into quantifiable metrics to make unbiased decisions.

Existing System Description

The below schematic illustrates the current LPG flare routing arrangement, wherein the underground LPG pipeline rises to above-ground level shortly before entering the flare stack.

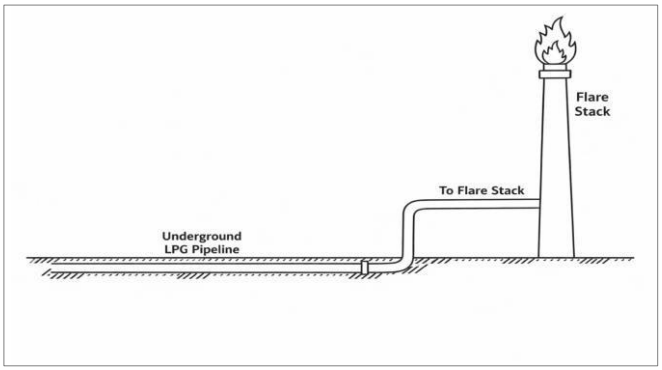

Figure 4.2.1 Design Layout - Current Scenario

Measure Phase

The Measure Phase is aimed at determining the inherent level of risk associated with emergency flaring occurrences without continuous monitoring and measuring with the aid of sophisticated equipment and quantitative emission logging. Thus, the significant characteristics of emergency flaring in remote SV stations are that it is irregular and not constantly monitored and analyzed with the aid of sophisticated and advanced analysis tools. Thus, the initial assessment of the structure is based on qualitative data obtained from site operations, records of maintenance, and opinions in quantifying factors. This approach ensures that qualitative data obtained from site operations are converted to quantified severity factors in the FMEA methodology. It does not mean that the structure can withstand external forces and that the design of the structure has been successful. It has been successful due to luck rather than inherent engineering resilience.

From the perspective of risk, the absence of a major failure does not automatically imply that the system is inherently

safe. A system that has not failed may still have underlying risks. To ensure an unbiased evaluation, established industry benchmarks were used to translate the qualitative data into quantitative data, as shown below.

Table 4.2.1: Qualitative-to-Quantitative Conversion - Current Scenario

S.No	Qualitative parameter	Conversion Technique used	Final Quantitative Output
1	Flame instability & smoke intensity	Ringelmann smoke index as per BS 2742-1969 standard	4 (Dense Bl;ack Smoke)
2	Possibility & Severity of catastrophic ground fire; detectability of liquid fallout	S-O-D Scoring as per IS 15550-2005 standard	Severity (S) = 10 Occurrence (O) = 3 Detection (D) = 7

Table 4.2.2: FMEA Scoring & Justification - Current Scenario

FMEA Element	**Scoring (Witness Judgment)**	**Justification**
Failure Mode	Liquid LPG reaches the flare tip (slugging/carryover).	
Failure Effect	Unstable flame, smoky combustion, Liquid LPG ground fire.	
Severity (S)	10 (Catastrophic)	Ground fire and loss of containment—maximum consequence.
Occurrence (O)	3 (Remote/Low)	Low frequency
Detection (D)	7 (Low)	Detection is reactive and post-event in nature, with no predictive instrumentation upstream of the flare.
Risk Priority Number (RPN)	S×O×D = **10× 3 x 7=210**	High RPN. While the frequency of event is low, the catastrophic severity mandates intervention.

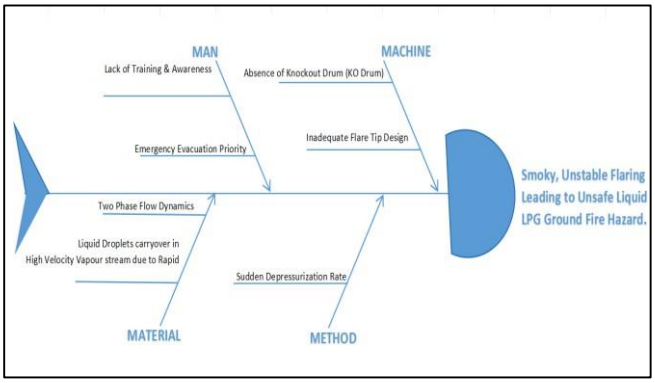
Analyze Phase

Quantitative data is considered for risk evaluation in the form of Risk Priority Number (RPN) by applying Failure Mode and Effect Analysis (FMEA) according to the IS 15550-2005 standard. Risk evaluation was performed by applying the Risk Priority Number (RPN) formula: RPN = S x O x D

Inference: The RPN value of 210 indicates a high-risk group, implying a situation that is not in compliance with the ALARP policy, which requires immediate action to lower it. The low-probability situation, rated at O = 3, although low, is not considered satisfactory due to the high severity, rated at S = 10, of the situation, which places it at a high level of risk exposure. In a risk-based evaluation, the severity of a situation is given considerable importance, and hence the situation under consideration cannot be considered satisfactory, even though it is a rare occurrence.

Ishikawa Analysis

The primary Effect (The Problem) is: Smoky, Unstable Flaring, resulting in an Unsafe Liquid LPG Ground Fire Hazard. There are various contributing causes, which are classified into four groups, namely Man, Machine, Material, and Method, which are all pertinent to pipeline operations.



This analysis indicates that the problem is not with the failure point but with the combination of human factors, equipment limitations, the thermodynamic properties of the LPG, and the procedures that are currently in place. From a human perspective, the emergency evacuation procedures focus on the rapid depressurization of the pipeline, even before the controlled flare process, and the lack of awareness about the effects of liquid fallout is a factor.

Table 4.2.3: Liquid Carryover - Cause, Analysis & Improvement

Category	Primary Cause from Diagram	Root Cause Analysis	Improvement Action
Man	Emergency Evacuation Priority	Emphasis is on speed of evacuation (safety of the line) over controlled flaring (safety of the unit).	Training on SOP & ensure compliance.
	Lack of Training & Awareness	Operators may not fully understand liquid fallout consequences.	Training on new KO Drum operation and SOP.
Machine	Absence of Knockout Drum (KO Drum)	Missing critical engineered barrier for two-phase flow. Leads to catastrophic failure severity.	Installation of a properly sized KO Drum with demister pad as per API 521.
	Inadequate Flare Tip Design	Tip is designed for vapor-only flow, leading to poor combustion when liquid slugs hit.	Flare tip modification rejected. Upstream liquid separation is the safer and ALARP-compliant solution.
Material	Two Phase Flow Dynamics	LPG is near its bubble point, highly susceptible to entrainment and mist formation.	KO Drum designed to provide sufficient residence time for gravity separation of bulk liquid.
	Aerosol/Mist Formation	Rapid expansion during venting creates fine liquid droplets (mist) that are easily carried by the high-velocity vapor stream.	KO Drum with Demister Pad specifically designed to handle fine mist separation.
Method	Sudden Depressurization Rate	High rates cause flashing, turbulence, and liquid slugging.	New SOP for mandatory review of rates.

Inference: Key takeaways from the analysis are as follows:

• Human and procedural factors are of minor significance.
• Two-phase flow and aerosol formation are thermodynamically intrinsic.
• In turn, the absence of a KO Drum signifies the sole missing engineered safety feature.
• Hence, we have a problem of design rather than behaviour.
• Under the 'Machine' category, the root cause of significant liquid carryover is directly facilitated by the 'Absence of KO Drum'.

Pareto Analysis

The following table depicts cause wise RPN contribution by the probable causes.

Table 4.2.4: Pareto Analysis of Causes Contributing to Unsafe Flaring

Cause	Severity (S)	Occurrence (O)	Detection (D)	Cause RPN
Absence of KO Drum	10 [Direct path for bulk liquid → catastrophic ground fire]	3 [Liquid carryover occurs during emergency venting only]	7 [No instrumentation to detect liquid before flare]	**210**
Two-phase flow dynamics	8 [Leads to unstable combustion & liquid fallout]	3 [Occurs whenever rapid depressurization happens]	6 [Visual detection only after flame instability]	144

Aerosol / mist formation	7 [Causes smoke, poor combustion, droplet fallout]	3 [Common during flashing LPG]	6 [Cannot be detected until mist exits flare]	126
Sudden depressurization	6 [Indirect contributor to flashing]	3 [Depends on emergency response]	5 [Detectable via pressure trend]	90
Operator prioritization	4 [Does not directly cause liquid carryover]	2 [Infrequent, training-dependent]	4 [SOP deviations detectable]	32
Procedural gaps	3 [Minor]	2 [Low]	4 [Auditable]	24

Total cumulative impact = 626

Table 4.2.5: **Cause wise RPN contribution**

Cause	% Contribution	Remarks
Absence of KO Drum	**33.5%**	Two-phase flow and mist formation are not independent failures; they are consequences of absence of KO Drum thereby resulting to cumulative contribution of **76.6%**
Two-phase flow	23.0%	
Mist formation	20.1%	
Sudden depressurization	14.4%	-
Others	9.0%	-

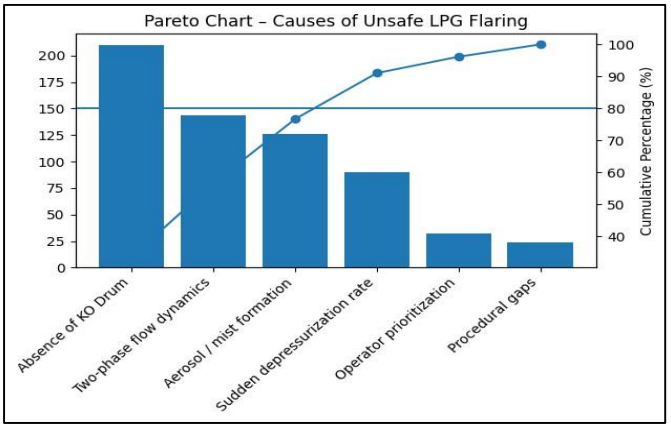


Figure 4.2.2: Pareto Chart- Cause vs RPN

The Pareto chart shows that the absence of the Knockout Drum, along with its direct consequences like two-phase flow instability and aerosol mist formation, causes 76.6% of the total cumulative risk exposure, i.e., 210 + 144 + 126 out of 626. However, these are not independent failure modes, and two-phase flow characteristics and aerosol mist formation are just thermodynamic consequences of improper upstream vapor/liquid separation. The Pareto analysis proves that the well-designed KO Drum solution will reduce 80% of the most dangerous risk of flaring through one single solution, and hence, from the risk-based decision point of view, it is not only the best solution but also ALARP compliant and financially viable.

Proposed Solution

The proposed solution would include the use of a horizontally oriented KnockOut Drum of sufficient size, to be installed ahead of the flare stack, and this design would be conducted in a conceptual manner following guidelines provided in the API 521 standard. The designed solution would include providing sufficient vapor residence time to allow vapor-liquid separation, a demister pad to account for liquid droplet removal, level transmitters with high-high level alarm to allow operation in a safe condition, and a flame arrestor to provide improved fire protection. The designed solution would include providing a definitive vapor-liquid separation barrier ahead of the flare, to "stop" liquid carryover and hence prevent unstable and smoky burning.

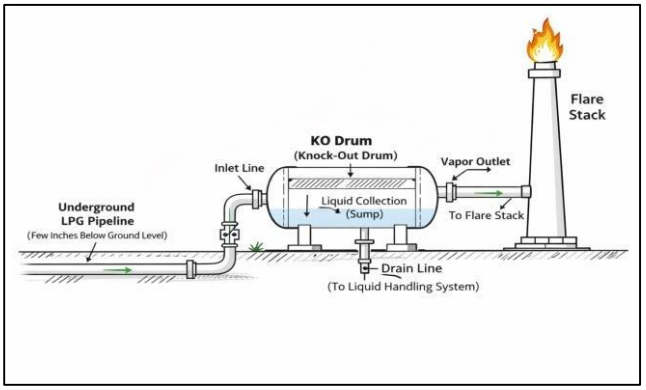

Figure 4.2.3: Design Layout – Proposed

The diagram above shows the recommended position of a horizontal Knockout (KO) Drum to be placed before the flare stack. The LPG vent pipeline from the underground location is directed upwards to connect to the KO drum inlet. The vapor from the KO drum passes through a mist eliminator section before proceeding to the flare stack, whereas liquid collection occurs and drains through a controlled outlet.

5.0 Summary of Findings

The study also verifies that the process safety risk arises from the presence of liquid LPG fires on the ground during flaring activities. Although these occurrences are rare, with only three occurrences in five years, the results from the FMEA indicated that the consequence of the event was catastrophic, as the Severity rating was given as 10. The results from the FMEA also indicated that the Risk Priority Number rating was initially given as 210, indicating that the system was in the zone of unacceptable risk.

The results from the Root Cause Analysis indicated that the main cause for the unstable combustion, smoke, and fires at the ground level during flaring activities was the liquid carryover during the rapid depressurization process. The results from the implementation indicated that the RPN rating had reduced to 30, indicating an 85% quantified reduction in risks. The Knockout Drum acts as a designed system to remove liquid carryover and mist from the system.

6.0 Suggestions and Recommendations

The results indicate that the implementation of the KO Drum needs to be standardized at all Sectionalizing Valve locations in the LPG pipeline system to ensure the consistent safety performance, especially in unmanned areas.

As a progressive Lean enhancement project, the technical feasibility of installing an LPG transfer pump to reinject the collected liquid LPG from the KO Drum into the downstream section of the pipeline can be considered. This project may help reduce flaring losses, improve efficiency in utilizing assets, and reduce hydrocarbon wastage in line with sustainability.

7.0 Conclusion

Within this research, it has been shown that operational problems within the low frequency domain can "hide" critical high severity process safety issues. By utilizing the Six Sigma DMAIC methodology, qualitative observational-based data has been transformed into quantifiable risk metrics.

Not only does the implementation of a KO Drum provide a mechanical solution, but it also provides a strategic solution to support Process Safety, Process Reliability, Regulatory Compliance, Environmental Regulations, Operational Excellence, and Asset Safety.

The main achievement of the study is the establishment of a replicable framework for risk-based enhancement in engineering, which may be applied to remote infrastructure, for instance, pipeline infrastructure, and similar high-risk industrial systems.

The project also supports the idea that proactive engineering plays an important role in the prevention of catastrophic process safety failures and in the integration of quantitative risk assessment and operations.

Role Of Auditor Independence In Ethical Financial Reporting

[1]Lakshmi B , [2]Sofia Vincent J , [3]Ilakeya U

[1,2]Assistant Professor, [3]Students , Department of Management Studies

Panimalar Engineering College, Chennai, India

ABSTRACT: **Trust in financial reporting is heavily dependent on the auditor independence, which is very significant to maintain integrity, objectivity and ethics in financial reporting. The study focuses on the importance of auditor independence in respect of maintenance of ethics in financial reporting with respect to client's perception about transparency, tax adequacy and reliability of financial statements with reference to ethical framework of Institute of Chartered Accountants of India (ICAI). The study is based on primary data of 60 clients. The non- parametric data of the study was tested by Kruskal-Wallis H-test and Spearman's Rank Correlation test. In this study, despite its limitations in terms of its scope, geographical coverage and small sample size, establishes that the clients hold high regard for auditor independence. We conclude our study by recommending measures to strengthen auditor independence in small and medium-sized audit firms so as to promote ethical financial reporting and to enhance the public trust.**

Key Words: Auditors' Independence, Ethical Standards, Financial Reporting, Client Perception, Non-parametric Analysis, Professional Ethics

1. INTRODUCTION

Auditing is a very important aspect of good corporate governance and financial reporting. It ensures that financial reporting is reliable, transparent and free from any bias. The concept of independence of the auditor is of very great importance and it is anchored on the principles of integrity and objectivity. Independence as a concept, therefore, refers to the mental attitude of independence. It is not a matter of compliance with statutory regulation. An independent auditor must be in a position to exercise his professional judgement free from bias, influence or pressure from any quarter. The ICAI Code of Ethics (2019) makes reference to independence of mind and independence in appearance. Independence of mind means that the auditor is able to exercise his judgement without bias. Independence in appearance means that the auditor is seen to be independent by others. These aspects of independence are very important in order to command confidence in the auditing process and to eliminate any element of bias or conflict of interest in financial reporting

The ICAI Code of Ethics offers a comprehensive ethical framework that aids auditors in maintaining professional conduct. This framework is rooted in five principles: integrity, which mandates honesty and transparency; objectivity, which guards against bias and undue influence; professional competence and due care, which necessitate the upkeep of technical expertise and diligence; confidentiality, which guarantees the secure management of client information; and professional behaviour, which encourages adherence to legal standards and bolsters the profession's credibility (ICAI, 2019).

The Code also requires a conceptual safeguard approach in which auditors are required to identify, evaluate and deal with potential threats to independence. These threats may be financial, as a result of pressure from the client, due to the length of the audit engagement and/or due to the performance of non-audit services. The auditor must deal with any threats either by removing them or by applying appropriate safeguards. Safeguards may include checking the audit with an independent expert or consultant, or by making disclosure in respect of any matters that could undermine auditor independence.

Auditor independence has been extensively discussed in many research studies. It is stated that the actual and perceived auditor independence has significant impact on the stakeholders trust in the auditing process. Beattie et al. (1999) and Quick & Warming-Rasmussen (2009) suggest that trust is usually damaged when auditor has long term relationships, becomes financially dependent on auditees and carries out extensive non audit services although auditor is formally independent. DeAngelo (1981) and Francis (2004) also linked auditor independence with auditor expertise, auditor professionalism, auditor responsibility and overall audit quality as well as stakeholders' trust in financial statements.

Auditor independence in India is governed by various provisions under the Companies Act, 2013; Income Tax Act, 1961; and the ICAI Code of Ethics, dealing with objectivity, statutory audits, tax audits, auditor rotation and prohibition on non-audit and non-audit fees that may lead to conflict of interest. This study investigated auditor independence from the client's perspective (individual as well as corporate) and examined the extent to which auditor independence impacts trust, accountability and adherence to accounting standards, particularly in the context of small and medium-sized audit firms (SMAF), an area that has been less explored in auditor independence studies which have concentrated more on auditors as well as regulators.

2. OBJECTIVE

The objective of this research study was to investigate the individual and business client's perception of auditor independence. It discussed in greater depth how these perceptions may affect the accuracy and ethical content of financial statements and tax returns, the threats to auditor independence, whether auditor independence would secure clients' confidence in the reliability of financial statements and tax returns. Finally, the study provided recommendations on possible measures that small and medium-sized audit firms can put in place to enhance auditor independence.

3. LITERATURE REVIEW

Independence, skills, ethics and good corporate governance are found to be dominant variables in all the reviewed literature which enhance audit quality and reliability of financial statements. Independence helps in bringing objectivity in audits, reduces earnings management and enhances stakeholders' confidence (Sawaya et al., 2025; Kurniawan, 2023). It is also found that skills along with industry specific knowledge enhances compliance with accounting standards and detects misstatements (Sawaya et al., 2025; Thooyamany & Balagobei, 2025). An audit quality is influenced by auditor related, client related and external regulatory factors (Fawziah et al., 2025). These factors often threaten audit quality such as non audit services, long auditor tenure, client's influence and auditor–client relationship (Wakil, 2021; Tepalagul & Lin, 2015; Zayol et al., 2017). It is also found that audit quality is also influenced by ethical standards and good corporate governance which enhances transparency and prevents audit misbehaviour (Riyadi et al., 2025; Jejeniwa et al., 2024). Financial scandals can occur due to poor corporate governance and unethical acts of auditors and management as depicted in Satyam case (Mishra & Umair, 2025). The regulatory framework is developing with independent regulatory bodies like NFRA to enhance accountability in auditing (Anil Kumar, 2018). The empirical studies as discussed above confirms that enhancing independence, ethics and regulations are necessary to enhance audit quality, investors' confidence and reliability of financial statements in various contexts.

4. RESEARCH METHODOLOGY

The study adopted descriptive research design in order to examine the perception of clients towards auditor independence. The study made use of both primary and secondary data. The primary data was collected using structured questionnaire whereas the secondary data was collected from various books, journals, reports and online sources. 60 respondents were selected using purposive non-probability sampling method. They were selected based on their knowledge on auditing profession. Non-parametric statistical tools such as Kruskal–Wallis H test and Spearman's Rank Correlation were used in order to determine the relationship and difference between the variables of the study. The whole methodology was done systematically in order to give the reader an easy interpretation of the findings which will relate to the objectives of the study. An additional thrust of this discussion is that awareness-building initiatives aimed at clients could serve to increase the awareness of other stakeholders of the protections in place to ensure auditor independence. The discussion also includes a comment on the auditor firms' policies being balanced in a way that enables a long term relationship between the auditors and clients and at the same time ensuring that independence protection is maintained.

5. DATA ANALYSIS

5.1 KRUSKAL-WALLIS TEST H-TEST

5.1.1 HYPOTHESIS 1

(H_0): There is no significant difference between the mean rank of men and women (gender) with respect to auditor independence while preparing financial statements.

(H_1): There is a significant difference between the mean rank of men and women (gender) with respect to auditor independence while preparing financial statements.

Table 1: Showing the Kruskal-Wallis test of association between Gender and the auditors' independence while preparing the financial statement

Test Statistics[a,b]

	Auditors' Independence while preparing financial statements
Chi-Square	.000
df	1
Asymp. Sig.	1.000

a. Kruskal-Wallis Test
b. Grouping Variable: Gender

Inference

Since the Kruskal-Wallis H-test using gender as the grouping variable was conducted, the results showed that the p-value for the tested objective was above 0.05 (e.g., 1.000), indicating that there is no statistically significant difference between the mean age of men and women in relation to the auditor's independence towards the financial statements. This suggests that age does not have a significant impact on auditors' perceptions of independence.

5.1.2 HYPOTHESIS 2

(H_0): There is no significant difference between the mean rank of respondents based on their years associated with the audit firm with respect to agreement on auditor independence.

(H_1)There is a significant difference between the mean rank of respondents based on their years associated with

the audit firm, with respect to agreement on auditor independence.

Table 2: showing the Kruskal-Wallis test of association between Years associated with the audit firm with respect to agreement on auditor independence

	Do you agree that your auditor maintains independence in their work
Chi-Square	6.194
Df	3
Asymp. Sig.	.103

Inference

The Kruskal–Wallis H-test using years associated with the audit firm as the grouping variable was conducted, and the results showed that the p-value for the tested objective was above 0.05 (0.380). This indicates that there is no statistically significant difference in perceptions of whether the auditor maintains independence in their work across clients with different lengths of association with the firm. In other words, the duration of association with the audit firm does not have a significant impact on how clients perceive auditor independence. Hence, we fail to reject the null hypothesis (H_0) and conclude that there is no significant difference in perceptions of auditor independence across the groups based on years of association with the firm.

5.1.3 HYPOTHESIS 3

(H_0): There is no significant difference between the mean rank of individual clients and business clients (type of client) regarding trust in financial statements when the auditor is independent.

(H_1)There is a significant difference between the mean rank of individual clients and business clients (type of client) regarding trust in financial statements when the auditor is independent.

Table 3: showing the Kruskal-Wallis test of association between types of client (Individual and business), regarding the trust in financial statement when the auditor is independent

	Do you trust your financial statements more when your auditor is independent?
Chi-Square	1.532
Df	1
Asymp. Sig.	0.216

a. Kruskal-Wallis Test
b. Grouping Variable: Type of client

Inference

The Kruskal–Wallis H-test using types of client (Individual or Business) as the grouping variable was conducted, and the results showed that the p-value for the tested objective was above 0.05 (0.216). This indicates that there is no statistically significant difference between trusting the financial statement when the auditor is independent and the type of client. In other words, the type of client in the audit firm does not have a significant impact on trusting the financial statement when the auditor is independent. Hence, we fail to reject the null hypothesis (H_0) and conclude that there is no significant difference; both clients show similar levels of trust in financial statements when the auditor is independent.

5.1.4 HYPOTHESIS 4

(H_0): There is no significant difference between the mean rank of respondents grouped by years associated with the audit firm regarding the belief that auditor rotation improves independence.

(H_1): There is a significant difference between the mean rank of respondents grouped by years associated with the audit firm regarding the belief that auditor rotation improves independence.

Table 4:Showing the Kruskal-Wallis test of association between years associated with the audit firm regarding the belief that auditors rotation improves independence

Test Statistics[a,b]

	Do you think rotation of auditors can improve independence?
Chi-Square	1.475
Df	3
Asymp. Sig.	.688

a. Kruskal-Wallis Test
b. Grouping Variable: Years

Inference

The Kruskal–Wallis H-test using types of client (Individual or Business) as the grouping variable was conducted, and the results showed that the p-value for the tested objective was above 0.05 (0.688). This indicates that there is no statistically significant difference between the rotation of the auditor can improve independence and the years associated with the audit firm. In other words, the years' association with the audit firm does not have a significant impact on the rotation of an auditor. Hence, we fail to reject the null hypothesis (H_0) and conclude that there is no significant difference.

5.1.5 SPEARMAN'S RANK CORRELATION

Independent variable: Years associated with the audit firm

Dependent variable: Do you think working with the same auditor for a long time affects their independence

Table 5: Showing the Spearman's rank correlation between years of association with the audit firm and working with the same auditor for a long time affects their independence.

Correlations				
			Years	Relationship
Spearman's rho	Years	Correlation Coefficient	1	-0.103
		Sig. (2-tailed)	.	0.432
		N	60	60
	Relationship	Correlation Coefficient	-0.1	1
		Sig. (2-tailed)	0.432	.
		N	60	60

Inference

- Correlation coefficient (ρ): –0.103 -very weak negative relationship.
- Sig. (p-value): 0.432 (> 0.05).
- N = 60.

The Spearman's Rank Correlation test was conducted to examine the relationship between the years clients were associated with the audit firm and their perception of whether working with the same auditor for a long period affects independence. The correlation coefficient ($\rho = -0.103$) indicates a very weak negative relationship. However, the significance value ($p = 0.432$) is greater than the 0.05 threshold, suggesting that the result is not statistically significant. Therefore, we fail to reject the null hypothesis (H_0) and conclude that the years of association with the audit firm do not have a significant influence on clients' perceptions regarding the impact of long-term auditor relationships on independence.

6. SUGGESTION

Audit firms must continue to seek to improve and to implement effective independence policies and procedures and we generally observe high levels of stakeholder confidence in audit processes. Rotations of audit firms may also be necessary to address potential threats to independence arising from familiarity. Audit firms must also continue to ensure that auditors undergo appropriate continuing professional education and ethics training to sustain their independence and objectivity.

Companies can increase stakeholders' confidence in their accountants and auditors by being more open about non-audit services such as financial consulting and by more clearly explaining steps they take to protect independence and comply with strict standards on that issue. The accounting profession also has the ability to police itself more effectively by requiring checks and balances, such as peer reviews, and conducting regular audits of its members' work.

Awareness of client feedback can also contribute to stakeholder understanding of the independence safeguards in place to protect auditor independence. Auditing firms may also wish to consider developing balanced policies which enable the development of long term auditor client relationships, while at the same time maintaining appropriate safeguards to protect auditor independence.

7. CONCLUSION

Trust is a basic component of any healthy financial system. The independence of auditors is key to providing assurance on reliability, integrity and quality of financial reporting. Our clients are satisfied with our professional and unbiased approach to their auditing requirements, which strengthens their trust in financial reporting. Auditors must adhere to internationally recognized standards of professional ethics and regulatory requirements, thereby maintaining their professional reputation and strengthening the trust of various stakeholders.

The report, which makes several key findings and recommendations, emphasizes that auditor independence is fundamental to assuring technical competence and maintaining auditor integrity and public trust. Clients have specifically recognized the importance of auditors providing their services impartially and in a highly professional manner. Overall, a strong auditor independence enhances financial market governance, increasing transparency, fairness and sustainability.

An Empirical Study On Loan: Portfolio In Financial Service Industry

[1] Dr D. Chitra

Professor[1],Department of Management Studies

Panimalar Engineering College, Chennai , India

ABSTRACT : **The makeup, performance, and risk exposure of Enterprise's loan portfolio are the main subjects of this study. The study evaluates the distribution of loans across different industries, credit quality, and payback trends in order to ascertain the benefits and drawbacks of the portfolio. Key financial metrics like sector diversification, loan-to-value ratios, and non-performing assets are used to assess the company's resilience and financial health. In addition to emphasizing aspects of effective credit management, the findings also point to possible hazards that could affect liquidity and profitability. The article's conclusion makes suggestions for loan portfolio optimization techniques that will enhance sustainability, lower default risks, and further long-term growth objectives.**

***Key words – Loan, Repayment, Profitability*.**

I.INTRODUCTION

The process of evaluating the performance, composition, and hazards of a financial institution's loans to its clients is known as customer loan portfolio analysis. In addition to revealing trends in repayment patterns, default rates, and credit quality, this study offers helpful information regarding the distribution of loans across numerous categories, including loan kinds, client demographics, industries, and geographic areas. Loan portfolio analysis helps financial institutions maximize portfolio performance, reduce risks, ensure regulatory compliance, and make well-informed decisions about future lending plans by utilizing data analytics and risk assessment tools. In the end, it improves the business's capacity to sustain consistent financial stability and long-term expansion.

Banks and lenders take a close look at their loan portfolios to understand the risks, performance, and mix of loans they hold. They do this through a process called loan portfolio analysis. This helps them spot patterns, figure out how customers tend to borrow and pay back, and get a real sense of the portfolio's overall condition. There are lots of ways to break down the data: type of loan, terms, interest rates, who the customers are, and how they handle repayments.Digging deeper, they pay attention to things like the loan-to-value ratio, non-performing loan (NPL) ratios, chances of default, and how much money the loans actually make. This way, they can find problem areas, predict losses before they happen, and fine-tune their credit policies.At the end of the day, loan portfolio analysis isn't just about managing risk — it's a key part of making smart, strategic decisions. It keeps lending practices in step with what's going on in the market and what regulators expect.

II. SCOPE OF THE STUDY

Banks really get into the weeds when they analyze their loan portfolios. They want to know everything—who's borrowing, what kind of loans they're handing out, whether those borrowers are likely to pay them back, how repayments are actually going, and where their money's scattered across regions. All this digging helps them catch warning signs early, spot patterns, and find chances to spread their risks around. But they don't work in a bubble—they keep a close eye on what's happening in the market, any fresh regulations, and the economy's mood swings. Those outside forces can shake things up fast. When banks piece together all these details, they end up with sharper strategies. They can tweak their risk game, decide where to invest more, or pull back—and the bottom line? Smarter decisions mean bigger profits and steadier finances.The Scope of the Study deals with the complexities of the financial institutions' assessment of the stability of the loan portfolio. The scope of the study includes an overall assessment of various aspects of the demographics of the borrowers, types of loans, and the possibility of repaying the loans, which are located in various geographic areas.

In other words, the research undertakes an in-depth analysis of the complexities of the operational process involved in the management of financial institutions in relation to the sustainability of financial portfolios. The research undertakes an in-depth analysis of the approval process in relation to the operation of various business sectors, as well as the interest rates associated with corporate entities in the financial services industry. The research undertakes an in-depth analysis of the various trends associated with the demographic structure of the borrowers, the nature of financial portfolios, as well as the repayment patterns in relation to specific regions, in order to identify the early signs to allow for effective diversification. The research undertakes an in-depth analysis of the external factors, which have a direct impact on the financial stability of the financial institutions, as well as the liquidity of the financial institutions, which in turn have a direct impact on the financial stability of the economy, considering the introduction of Basel III. The scope of the study deals

with understanding the various business sectors that are approved for loans, corporate interest rates, and the financial services industry.

III. OBJECTIVES OF THE STUDY

1.To understand how different business sectors are approved for loans.
2. To determine the corporate interest rate.
3. To look into the repayment practices of the financial services sector.
4. To examine the actions taken to evade repayment.
5. To make recommendations and suggestions about the expansion

IV. NEED OF THE STUDY

Loan portfolio analysis is an important need for financial institutions to assess the performance, composition, and inherent risks of lending activities. The need for banks to identify patterns of customer behavior, through the application of data analytics tools, in a dynamic financial environment cannot be overstated. The need to understand loan patterns, along with other important ratios, such as loan-to-value ratios, non-performing assets, etc., is important to identify areas of concern and to anticipate any possible losses that may be incurred in the near future. The study of loan portfolio analysis is important to help financial institutions respond to external factors, which affect financial institutions, such as market trends, economic fluctuations, and other regulatory issues, including Basel III. The deeper understanding of loan portfolio analysis, with regards to various business sectors, will help financial institutions improve their credit policies, comply with regulations, and sustain financial stability, which is important for financial institutions to achieve in order to ensure profitable growth.Further, there is a need to critically assess how financial institutions are able to provide their clients with appropriate instructions and personalized guidance on how to manage their loans.

V. LIMITATIONS OF THE STUDY

The primary need for this study arises from the importance of loan portfolio analysis in the financial health and well-being of the enterprise. In the current financial service industry, which is highly volatile, it is imperative for financial institutions to look beyond the conventional and dive deep into the analysis of sectoral diversification, loan-to-value ratios, and non-performing assets to ensure the long-term sustainability of the enterprise. This study is the need of the hour to create a roadmap for optimizing the loan portfolio, which in turn would help in mitigating the risk of default and enhance the overall liquidity and profitability of the lender.Moreover, the need to understand the human aspect of the financial services industry is the need of the hour. This study attempts to understand the correlation between the communication skills of the lenders and the satisfaction of the client's financial demands, creating a vital link in the chain of building the much-needed trust with the customers. This study is the need of the hour to bridge the gap between the complex rules and regulations, such as Basel III, and the actual operational management of the financial services industry.

However, the results of this study are also bounded by a number of constraints, most significantly in terms of the sample size and the method of data collection itself, which was conducted after a final sample of 97 valid responses out of a total of 107 was obtained, and in light of the unknown total population, which necessitated a pilot study of only thirty customers in order to develop statistical baselines.

Moreover, the results of this study are also bounded by its descriptive nature as a type of research, which seeks to describe characteristics as they naturally occur without any external variables influencing the outcome, and which, as a result, cannot hope to prove any direct causation between any of the lending policies and economic outcomes.

VI. REVIEW OF LITERATURE

David Martinez (2021) , David Martinez studied the effect of Basel III rules on the risk of banks' loan books in 2021 and concludes that Basel III rules, by requiring more capital, definitely reduce risk but also tend to make banks lend less. Martinez main message is quite clear regulators have to find the right level of regulations. He advocates a fine-tuning where financial stability is not at the expense of economic growth slowdown. If you want to see how regulation influences risk management, this paper is a must read.

John D. Smith, (2023) Research in loan portfolio analysis fundamentally relies on the methodology developed by Smith (2023) that stress the importance of quantitative tools in the measurement and management of risk (Smith 2023). The present research relies on the application of statistical models as tools to direct decision making for the credit risk management in the "loan portfolio" (see section 4.1). Smith (2023) pays special attention to the integration of different sources of information of the borrower with macroeconomic variables, so as to modify the model according to the macroeconomic cycle and to take into account the systemic risk. Traditional credit scoring models are criticized for not being able to tell systemic risk, which is what this research intends to do. This line of research would be very useful for financial institutions willing to improve their credit risk management systems.

Michael Brown (2016) Brown explores the control of credit risk with credit derivatives such as credit default swaps (CDS). It points out the risk spreading aspect of these derivatives and also warns of systemic faults. Greater market regulation and more information on credit derivatives are things he believes in. To understand the sophistication of the financial instruments used today this is an important research.

VII. RESEARCH METHODOLOGY

The research methodology for this particular study is based on a descriptive research design, which aims to study the characteristics of the loan portfolio and customer behavior as they occur naturally without manipulating the variables. In order to make the study statistically significant and free from any kind of biases, the researcher opted to use the random sampling method, which allows every individual in the population to have an equal chance of being selected. Since the population for the study was not known, the researcher conducted a pilot study of thirty customers to find the value of 'p' and determine the ideal sample size.The researcher collected the data from the population using primary sources, structured surveys, and questionnaires to obtain accurate and relevant information from the selected population. Out of the total population, the researcher received 107 responses, but only 97 responses were used for the study, allowing for a margin of error. The researcher used the quantitative method and the Chi-Square test to determine the relationship between lender communication and customer satisfaction.

RESEARCH DESIGN

The goal of a descriptive study is to portray systematically a population situation or phenomenon and variables are not manipulated. The main goal is to portray events actions or characteristics as they normally. Its primary objective is to accurately and completely depict events, actions, or characteristics as they naturally occur.

SAMPLING TECHNIQUES

The random sampling a type of probability sampling method was used for selection of sample. When random sampling is used, all persons in the population have an equal chance of being chosen. This method reduces bias and increases the representation of the entire population in the sample. Statistical soundness and generalizability of the research results can be obtained by random sampling. Random sampling is most appropriate for research that aims at generalizability of research results in large adult population studies/clinical trial/surveys, hospital based studies, field studies, and following other sampling methods where a complete list of the population is available.

POPULATION SIZE

The responses to the poll came from different customers. A pilot study of thirty customers was used because the population was unknown. The results of this pilot study were used to determine the value of p. Therefore, 97 is the ideal sample size.

DATA COLLECTION

The primary sources of the study's data were the individuals that were chosen. To ensure accuracy while accounting for a margin of error, the study used 97 of the 107 replies that were collected. Surveys and questionnaires were used to guarantee the accuracy and relevance of the data gathered for the study.

VIII. ANALYSIS AND INTERPRETATION

CHI SQUARE TEST

The Chi Square Test, as used in this particular study, is a statistical tool used to ascertain if a particular relationship exists between two variables. As used in this particular study, the researcher used the Chi Square Test to ascertain if the lender's communication style, as exemplified by the provision of instructions, has a direct bearing on the client's perception of their needs being met. By comparing the results of the responses from the customers to the expected results if no relationship existed, the researcher was able to ascertain if the results were purely by coincidence or if a relationship existed. As used in this particular empirical study, the researcher used a 5% level of significance. As a result of the Chi Square results, which had a p-value of 0.000, the researcher was able to reject the null hypothesis and ascertain that the relationship between the provision of clear and precise criteria for paying the loans and customer satisfaction was statistically significant, as the p-value was well below 0.05.

NULL HYPOTHESIS

H0: There is no relationship between the lender's provision of clear instructions to clients regarding how to manage loan repayments and the perception of clients that their financial demands are adequately satisfied during the process**.**

ALTERNATIVE HYPOTHESIS

H1: There is a relationship between clients' perception that their financial demands are sufficiently satisfied during the process and the lender's provision of clear instructions regarding how to manage loan repayments.

Chi-Square Tests

	Value	d.f	Asymp. Sig. (2-sided)
Pearson Chi-Square	150.752[a]	8	.000
Likelihood Ratio	131.296	8	.000
Linear-by-Linear Association	76.571	1	.000
No of Valid Cases	97		

a. 11 cells (73.3%) have expected count less than 5. The minimum expected count is .08.

INTERPRETATION

Since p=0.000, we can conclude that we should accept the alternative hypothesis at a 5% significance level. It can thus be argued that there exists a link between the lender's specific loan repayment criteria and the opinion of the customers that their financial needs are satisfied during the process. There exists a high level of correlation between the opinions of the customers regarding the clarity of the loan repayment criteria and the opinion of the customers that their financial needs are satisfied. It, therefore, becomes apparent that financial help plays a critical role towards the happiness of the customers. Lenders should, therefore, concentrate on offering personalized financial advice, ensuring that the borrowers understand the loan repayment criteria, as well as the transparency of the loan.

IX. FINDINGS

A fair view of loan-related issues was provided by the study participants, who were comprised of 54% men and 46% women. The fact that 54% of the study participants are in the 25-34 age group, while 23% are in the 35-45 age group and another 23% are in other age groups, reveals that more young people are more interested in lending.

The study findings show that most study participants strongly feel that they are provided with accurate information regarding the terms and conditions of the loan and that the loan application process is easy to understand. Furthermore, most study participants demand that the loan approval procedure is conducted in a timely manner and that sufficient customer service is provided. In addition, most study participants believe that the procedure sufficiently satisfies their financial needs.
Most study participants indicated that interest rates are adequate, appropriate, and easy to understand. However, some study participants are of the view that interest rates are high and do not provide sufficient benefits.

Despite this, most customers are satisfied with the interest rates and are willing to let other people know about their lender. Most consumers believe that the interest rates provided by the lender are fair. Many customers believe that the rates offered by the lender are reasonable. The customers' perception of clear guidance in loan repayment and their perception that their financial needs have been sufficiently met were found to have a significant correlation ($p = 0.000$, $p < 0.05$). This illustrates the significance of customer satisfaction and happiness and the need to build customer trust through proper management of customer loans. A statistically significant correlation between customer assistance for loan repayment issues and satisfactory customer service during the loan approval process is evident in the data ($p = 0.000$, $p < 0.05$). This illustrates the significance of building customer relationships throughout the entire loan approval and repayment process to ensure customer satisfaction and build customer trust.

X. SUGGESTIONS

➢ Launch awareness campaigns to enlighten borrowers on the various loan facilities and repayment strategies to minimize default.

➢ Emphasize the advantages of timely loan repayment to help borrowers sustain a financially stable position and a higher credit rating.

➢ Urge consumers to seek financial guidance to improve the quality of loan repayment strategies.

➢ Emphasize the significance of effective loan repayment and financial management to support economic development and financial stability of the banking industry.

➢ Acknowledge the difference in the ability to repay loans depending on various factors, such as income and employment levels; therefore, financial guidance should be tailored to suit individuals.

➢ Keep the borrowers abreast of the changes to interest rates, loan repayment strategies, and restructuring facilities to enable them to make informed decisions.

➢ Develop accessible online resources to guide borrowers on the management of loans, repayment schedules, and EMI calculations.

XI. CONCLUSION

In order to give both lenders and borrowers financial stability, this study emphasizes the significance of loan portfolio analysis. As the lending market expands, clear loan terms, customer-friendly legislation, and effective loan administration are essential components. Lenders may be able to maintain profitability, improve client happiness, and prevent loan defaults with an effective loan portfolio. Lenders may be able to improve loan repayment alternatives, interest rate competitiveness, and loan processing speed by utilizing data-driven strategies.This advertisement shows the importance of borrower education, digital transformation, and transparency of financial processes. The financial stability of the economy can be improved through fair terms of lending, communication, and flexible terms of payment that can build confidence among borrowers. In today's fast-moving financial world, proper management of loans can benefit both lenders and borrowers and help build a more stable and equitable financial system. Financial institutions can increase productivity and minimize risks to help the economy through the implementation of the recommendations of the research study.The study's findings have so emphasized the significance of loan portfolio analysis, which is necessary to provide a stable financial environment in a changing climate for both the borrower and the lender. This study has emphasized the importance of transparent loan regulations, legislation, and procedures that were formerly voluntary but are now required to create a financially sound banking environment due to the financial industry's increasing complexity. Financial institutions can now successfully sustain their profitability while raising client satisfaction and reducing the risk of loan default by using data-driven initiatives.

Post Interaction Communication And Niche Talent Retention :

A Longitudinal Study

[1]Dr.M.Beulah Viji Christiana

[1]Professor, Department of Master of Business Administration

Panimalar Engineering College, Chennai

Abstract : **The purpose and aim of the study are to evaluate the effectiveness of the application of the concept of strategic follow-up communications in enhancing candidate retention during the recruitment process for niche IT skills. The study in particular focuses on the important aspects that may improve candidate retention during the recruitment process for niche IT skills. The research design to be employed in the study is longitudinal in nature. The study focuses on the candidate response and organizational response during a specified period. The study also includes the application of surveys and interviews from the candidates and professionals for niche IT skills at various stages during the recruitment process. The research design to be employed in the study is descriptive in nature. The data for the study is both primary and secondary in nature. The sample size for the study is 250. The non-probable sampling technique to be employed in the study is convenience sampling. While evaluating the data collected for the study, appropriate statistical tests such as correlation tests and comparative tests may be employed to evaluate the results obtained for candidate retention and strategies for follow-up communications.**

Key Words: Communication channels, Frequency, Personalization, Timeliness, Content, Candidate Retention.

INTRODUCTION

In the highly interconnected and digitalized world economy, in which technological advances are happening at unprecedented rates, the requirement to attract and retain the best talent has assumed significance in the sustenance and success of competitive advantage in organizations. This is especially true in the information technology industry, as it is known to be one of the most dynamic and ever-changing industries. It is one industry in which specialized skills are the key to success and leadership in the industry, and the requirement to acquire competent information technology professionals to solve increasingly complex technological problems has been outgrowing the supply, creating a highly competitive requirement to acquire such skills. Requirement to acquire specialized skills is especially true when one considers the variety of skills that are in demand, such as Artificial Intelligence, Cyber Security, and Cloud Computing, as they are known to be highly complex and require constant learning, creating a unique challenge for organizations to attract and retain such talent. In this highly competitive and candidate-driven marketplace, the experience of the prospective employee plays a pivotal role in decision-making, and decisions are made based upon the candidate experience.

The aspect of follow-up communication, which represents the effective and significant interaction between the organization and the candidates from the time of initial contact until the final decision, has the potential to impact candidate engagement, professionalism, and even the final decision-making process to a significant extent. However, the specific aspects of effective follow-up communication, including the communication medium, frequency, content, and personalization, must be understood in detail, especially when it comes to the domain of IT recruitment. In order to bridge the gap in the existing literature, the present study aims to assess the effectiveness of strategic follow-up communication in enhancing candidate engagement during the recruitment process for niche IT positions. The main objective of the proposed study is to provide a detailed analysis of the impact of effective communication strategies, implemented at different stages of the recruitment process, on candidate engagement and their willingness to take up the offered positions.

OBJECTIVES :

- To determine the communication channels through which frequency increases candidate engagement at various stages of the niche IT skills recruitment process.
- To assess the level of personal feedback and timely updates considered important by candidates with niche IT skills at various stages of the recruitment process.
- To analyze the link between the promptness of communication and the perception of candidates regarding organizational responsiveness and professionalism.
- To determine the impact of the content of communication on the decision-making process of candidates with niche IT skills.
- To assess the long-term impact of positive communication in follow-ups on candidate referrals and organizational brand perception, even for unsuccessful candidates.

NEED FOR THE STUDY :

In the highly competitive niche IT skill recruitment market, candidate retention has now become an important factor in organizational success. The role of strategic follow-up communication in shaping the perception of candidates about an organization's professionalism and responsiveness in the recruitment process is significant. Professionals in niche IT skills are highly in demand and are usually extended multiple job offers. It is important to understand the impact of personalized communication in the candidate's selection process. This study intends to investigate the impact of strategic follow-up communication in candidate retention during the recruitment process, as per the primary objective of the research.

Moreover, it is important to identify the communication methods that are most effective in engaging niche IT candidates at different stages of the recruitment process. This also addresses the first secondary objective of the research. The study also intends to identify the perception of candidates regarding the value of personalized feedback and timely updates in the recruitment process. This addresses the second secondary objective. Moreover, the study also intends to identify the relationship between the timeliness of follow-up communication and candidates' perception regarding organizational professionalism and responsiveness. This addresses the third secondary objective.

SCOPE OF THE STUDY :

The scope of this study is restricted to the recruitment of IT professionals with specific skills sets in the field of IT, namely AI/ML professionals, cybersecurity professionals, and cloud computing professionals. The study focuses on the practices of follow-up communications during the entire recruitment process, from initial stages to final stages of recruitment. The sources of data collection for this study will be candidates who are undergoing the recruitment process for specific IT skills sets and recruitment professionals who are involved in the recruitment process for these candidates. The geographical scope of this study includes organizations that are functioning in specific regions, namely North America and Europe. The subsequent sections of this study will provide a detailed explanation of the literature review, research methodology, analysis and interpretation of the study findings, and implications of the study.

This study focuses on the effectiveness of the follow-up communication process adopted by recruitment firms in the placement of these highly sought-after candidates in the IT industry, in line with the major objective of evaluating the efficacy of strategic follow-up communication in retaining candidates. The geographical scope of this research would be limited to the regions where the recruitment agency actively recruits niche IT talent. In addition, the research would also examine the long-term impact of positive follow-up communication in terms of candidate referrals and employer branding, even for those candidates who do not make it to the final selection. Moreover, the research would also examine the impact of the timing of follow-up communication in relation to candidates' perceptions of organizational responsiveness and professionalism, as well as the impact of follow-up content on candidate decision-making.

REVIEW OF LITERATURE :

Recently, literature has also identified the significance of candidate-centric recruitment practices and communication in the recruitment process. Davis & Clark (2025) have discussed the evolution of the recruitment process from a transactional approach to a relational approach based on transparency and communication with the candidate in the recruitment process. Smith & Johnson (2024) have also discussed the evolution of the recruitment process from a relational approach to a relational approach based on communication with the candidate through emails and chatbots in the recruitment process. Nguyen & Chen (2025) have identified the importance of using artificial intelligence tools such as chatbots and predictive analytics in speeding up the recruitment process and communication with the candidate in the recruitment process to recruit technology professionals. Moreover, Kim & Lee (2024) have identified the significance of social media communication in the recruitment process.

There are many studies that have proven the significance of personalization, feedback, and communication in the decision-making process of candidates. Bennett & Harris (2024) found that personalization in communication has a significant positive impact on candidate satisfaction and employer branding. Another study was conducted by Garcia & Patel (2024) to show the significance of personalization in communication, especially in follow-up communication to recruit candidates with specific skills in a specific domain. Davis & Martinez (2024) found that feedback has a significant positive impact on the decision-making process of candidates in a competitive job market. Another study was conducted by Lee & Wilson (2023) to show the significance of communication in improving the candidate experience process. This idea was supported by another study conducted by Lee & Kim (2023), in which the researcher found a strong positive relationship using a meta-analytical method.

This is clearly seen in the study by Patel and Brown (2024) that clearly indicates that the chances of getting a referral and brand advocacy from the candidates are enhanced by a positive candidate experience. Brown and Wilson (2022) also clearly indicated that the chances of the candidates advocating for the organization to other people are enhanced if the candidates had a positive communication experience with the organization, even if they do not get the job they had applied for. Moreover, the importance of communication was also clearly seen in the study by Wilson and Taylor (2023) that clearly indicates the importance of communication in building trust between the organization and the candidates, thus enhancing the chances of a successful recruitment drive by the organization. The importance of employer branding was also clearly seen in the study by Moore and Clark (2022)

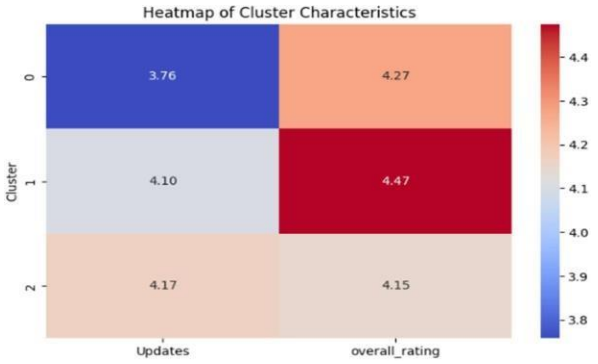
that clearly indicates that it is very crucial in shaping the perception of the candidates and enhancing the chances of the candidates accepting the job offer from the organization. The importance of communication was also clearly seen in the study by Rodriguez and Hernandez (2022) that clearly indicates the importance of a culturally sensitive communication approach.

RESEARCH METHODOLOGY:

Research Design study is descriptive. Data collected were both primary and secondary in nature. Primary data are collected through a structured questionnaire and secondary data are collected from various magazines , reputed journals, previous researches conducted etc. Sample Size is confined to 250 and convenience sampling which is a non-probability sampling techniques is adopted. Various statistical tools like chi square test, multiple linear regression, spearman's rack correlation, logistic regression and linear regression.

ANALYSIS & INTERPRETATION:

TABLE 1: Cluster Analysis of Communication Style and Engagement Metrics



Clusters	Preferred contact	Update frequency	Update Stage	Engagement
0	LinkedIn messaging	3.758065	Post-Interview	4.274194
1	Phone	4.102564	Post-Interview	4.474359
2	LinkedIn messaging	4.166667	Offer Stage	4.145833

TABLE 2 Preferred Contact Method on the basis of candidates' experience

Level	Email	LinkedIn messaging	Phone	Text
Entry Level	16	20	30	7
Lead Level	7	7	15	12
Mid Level	12	23	25	7
Senior Level	14	25	20	10

K-means clustering (k = 3) was used to categorize respondents based on their communication preferences, identifying distinct groups with differing preferred contact methods, average desired update frequencies (approximately ranging from 3.76 to 4.17), and specific recruitment stages where frequent updates were considered most important. These clusters also demonstrated variation in average engagement levels, with overall follow-up ratings ranging from about 4.15 to 4.47.A Chi-square test ($\chi^2 = 16.901$, $p = 0.153$) revealed no statistically significant relationship between preferred contact method and overall follow-up communication ratings. Furthermore, it was also found that Phone and LinkedIn messaging were the most favored communication channels for all levels of candidates, whereas Email and Text messaging were the least favored communication channels for the candidates.Another Chi-square test was performed to check the significance of the relationship between the candidates' primary skill level and their most favored communication channels for recruitment purposes.

From this Chi-square test, it was found that there was no significant relationship between the candidates' primary skill level and their most favored communication channels for recruitment purposes, as $\chi^2 = 13.909$ and $p = 0.126$.It was interesting to note that whereas Cluster 0 and Cluster 2 had found LinkedIn messaging as their most favored communication channels for recruitment purposes, there were differences found between Cluster 0 and Cluster 2 in terms of average desired frequency of updates (3.76 and 4.17), stages of updates considered most important (Post Interview and Offer Stage), and average engagement score (4.27 and 4.15).

Table 3: Multiple Linear Regression - Variance Inflation Factors

salary_job_details	104.036239
client_details	10.456596

In addition, Spearman rank correlation analysis showed that candidate satisfaction was statistically significantly and positively correlated with candidate satisfaction and perceived personalization ($\rho = 0.286$, $p < 0.001$), candidate satisfaction and perceived value of timely feedback ($\rho = 0.271$, $p < 0.001$), and candidate satisfaction and perceived importance of salary/job details ($\rho = 0.265$, $p < 0.001$). However, the Variance Inflation Factor (VIF) values

indicated that there was a high level of multicollinearity among the predictor variables in the regression model with regard to timely feedback and salary/job details (VIF = 109.06 and VIF = 104.04, respectively).

The results of the multiple regression analysis showed that the predictor variable of perceived personalization was a statistically significant predictor of candidate satisfaction (coefficient = 0.1524, p = 0.005). However, timely feedback, salary/job details, and client-related information did not show a statistically significant effect on candidate satisfaction in this study. This might have been due to the high level of multicollinearity that was present among the variables in the regression model, which might have made it difficult to show a statistically significant effect of timely feedback and salary/job details on candidate satisfaction, although timely feedback and salary/job details had shown a statistically significant.

Table 4: Candidates' Satisfaction - Spearman rank correlation

Relationship	Correlation Coefficient	P-value
Satisfaction vs. Timeliness	0.113	0.075
Satisfaction vs. Professionalism	0.136	0.032
Satisfaction vs. Responsiveness	0.17	0.007

The professionalism of Raad7 Informatics was ranked as the best in the communication style of Raad7 Informatics, followed by Responsiveness, and then Timeliness. This shows that all the candidates ranked Raad7 Informatics as high in professionalism. At the same time, it also shows that the least ranked was Timeliness in the communication style of Raad7 Informatics.Statistically significant positive monotonic relationship was established between Timeliness and Responsiveness by Spearman's rank correlation coefficient. This shows that even though the candidates ranked Responsiveness as a positive attribute in the communication style of Raad7 Informatics, it was ranked as a positive attribute in their communication style and was significant at 0.001.

Table 5: Feature Importance – Logistic Regression

Feature	Coefficient	Absolute Coefficient
FeedBack	0.148282	0.148282
Salary & Benefits	0.13261	0.13261
Technical Details Addressed	0.113973	0.113973
Insights on Client and Project	0.047684	0.047684
Personalisation	0	0

The monotonic relationship between Timeliness and Professionalism, which was found to be 0.106 with a p-value of 0.095, was not found to be statistically significant. Also, the relationship between Professionalism and Responsiveness was found to be 0.036, which was not found to be statistically significant since the p-value was 0.570. This shows that there was no significant relationship between these variables. This further shows that even though professionalism was rated the highest among all the variables, there was no significant relationship. However, timeliness has a positive effect on responsiveness.

The logistic regression model used to predict factors influencing the decision has been found to be 77.3% accurate. A very high bias was found since all the test data were classified as 'Influenced.' A classification report was obtained, which showed perfect recall but zero precision for 'Not Influenced.' A confusion matrix was obtained, which showed all instances were classified as 'Influenced.' The features which were found to be the most influential in the decision-making process were obtained from the L1-regularized logistic regression coefficients. They were found to be: Feedback (0.148), Salary & Benefits (0.133), Technical Details Addressed (0.114), Insights on Client and Project (0.048).

FINDINGS:

- K-means clustering for k=3 formed clusters for the respondents on the basis of communication preference, average desired frequency of updates ranging from 3.76 to 4.17, and primary stages in the recruitment process for the most important updates. The clusters were also formed on the basis of the level of engagement for the candidates with the communication. This was done on the basis of average ratings for the overall follow-up communication, ranging from 4.15 to 4.47.

- Chi-square test results were obtained to check the statistical significance for the difference between the most preferred mode of communication and ratings for the overall communication for the purpose of follow-up communication with the candidates. The results indicated that there was no significance between the two variables, as indicated by χ^2=16.901 and p=0.153.

- Primary skill levels for the candidates were also analyzed and indicated that Phone and LinkedIn messaging were the most favored for all levels, whereas Email and Text messaging were the least favored for the candidates.

- Spearman's rank correlation test was conducted to check the correlation between candidate satisfaction and primary skill levels for the candidates with the following variables: candidate satisfaction and personalization (ρ=0.286 and p<0.001), candidate satisfaction.

- The candidates rated the two factors highest in the aspect of Professionalism, followed by Responsiveness and then Timeliness, as indicated by the mean value of 3.91, 3.69, and 3.51, respectively. This indicates that the candidates perceive the hotel as very professional but somewhat lacking in timeliness.

- The linear regression analysis indicated that there is no significant relationship between the follow-up rating and the candidates' willingness to refer others to the hotel, as indicated by a coefficient value of -0.0244 and an R^2 value of 0.000 with a p-value of 0.737.

RECOMMENDATIONS:

The improvement of the timeliness of communication at all phases of the recruitment process can also lead to a better candidate experience and perception. More attention should also be given to the optimization of communication through the phone, given the high preference of candidates for communication through this medium, and recruiters should be trained to be more effective in communication with candidates. Another way to improve the candidate experience is to introduce a system of updates, especially at the post-interview phase, to manage candidate uncertainty better.

CONCLUSION:

The comprehensive feedback from candidates based on five major objectives provides valuable insights to improve the hiring process as well as candidate experience. Overall results consistently highlight the need to emphasize personalization and candidates' feeling of being understood in terms of candidate satisfaction, which supports existing literature on the need to adopt personalization approaches in talent acquisition.

While factors such as feedback, personalization of salary, and job-related information show positive correlations with candidate satisfaction, results from regression models reveal a dampening effect of these factors, which may be a result of multicollinearity between variables. Overall results strongly suggest the need to adopt personalization approaches in terms of candidate communication, ensuring that candidates feel understood throughout the hiring process, which is in line with candidate-centric approaches to talent acquisition.

A Study On The Impact Of Movies And Webseries On Socio - Emotional Intelligence On Gen Z In Chennai

[1]E. Rajeshwari, [2]T. Rithiga, [3]J. Jerita Esther, [4]V. Vishali, [5]S. Uma Mageshwari, [6]P. Lavina

[1, 2, 3, 4, 5, 6] MBA Student, Panimalar Engineering College, Chennai-600 123.

ABSTRACT: The rise of digital media has resulted in an increase in the viewing and streaming of movies and web series, which is affecting the socio-emotional intelligence of youth in Chennai. The analysis was conducted by using a questionnaire for the age group between 15-30 years to understand the impact of media on the youth. The analysis also determines the impact of media, including its negative and positive effects, on the youth, such as their understanding and sensitivity towards emotions and maturity, and how it leads to desensitization and expectations and aggression. This study helps us understand how we, as parents and teachers, should promote and create more content for the better socio-emotional intelligence of our youth. The study also helps us understand how we should consume media to become well-rounded and emotionally intelligent individuals.

Keywords: Digital Media Consumption, Web Series, Socio-Emotional Intelligence. Emotional Maturity, Social Cognition, Desensitization, Aggressive Behavior, Media Psychology.

1. INTRODUCTION

Digital media is greatly impacting entertainment, and movies and web series are available on phones. Among the youth in Chennai, this is impacting their thoughts, emotions, and behavior. Movies and web series are not just for entertainment. They are for emotions, relationships, and life experiences. They are impacting young minds in terms of managing their own emotions.

Socio-emotional intelligence, or the ability to understand and manage emotions and empathize with other people, is very important in adolescence and young adulthood. Media influences can have a positive effect on emotional intelligence, empathy, and social skills, or a negative effect on behavioral development depending on what is being shown. Web series, due to their narrative extent, provide greater opportunities for emotional engagement than a movie, which can influence attitudes, values, and social interactions in the long run.

In the case of the city of Chennai, the availability of high-speed internet coupled with the urban lifestyle ensures the easy availability of digital media. The availability of both local and global content ensures the exposure of youth to multiple cultural perspectives, thereby affecting socio-emotional development. Such emotional connections with the character may have a positive or negative influence on the viewer.

Youth have the tendency to develop behaviors, attitude, and emotions based on the content of the digital media they are exposed to. Such content, if it promotes the development of compassion, teamwork, emotional intelligence, or other positive traits, may have a positive influence on the viewer, whereas the opposite may lead to negative influences.

This study aims to explore the influence of movies and web series on the socio-emotional intelligence of young people in Chennai. It is a significant area of investigation, as understanding the influence of such media on young people can help in promoting responsible media consumption among them. It can help in their socio-emotional development in a digitalized world.

2. REVIEW OF LITERATURE

A few research studies emphasize the increasing popularity of OTT platforms and web series among the young population of India. According to Anindita Chattopadhyay, "With the advent of affordable internet and smartphones, binge-watching has become popular. The psychological and social behavior of youth have been impacted because of this binge-watching habit. Kuldeep Kumar's research study revealed that web series have become one of the major sources of entertainment for youth. The storylines of web series have been creative and realistic. Makwana Anjana's research study revealed that excessive viewing of web series can lead to obsession among the young population of the country."

Research carried out by Hafiza Khadija Azeem indicates that crime content on platforms like Netflix may promote aggression, depression, and negative behavioral traits among the 15–25 age group of the youth population. Mahalakshmi U.N states that the COVID-19 pandemic saw a rise in the consumption of OTT content among students in the state of Tamil Nadu, and binge-watching had a negative impact on the health, academic, and

behavioral aspects of the students. Sakshi Singh Bais confirms that binge-watching OTT content may have a negative impact on sleep, increase anxiety levels, and reduce social interaction, thus the need for the audience to be aware of healthy viewing habits.

As per the study done by Tarini Khosla, the audience is moving from cinema to OTT platforms due to their convenience and affordability, and web series are replacing traditional cinema viewing. Pari Mehrotra's study revealed that the impact of Western web series on school-going teenagers was positive, as it influenced their academic life and higher education in Western countries, but did not promote any negative behaviors in their lives.From the above literature, it is revealed that although the content on OTT platforms is engaging and provides knowledge, the improper viewing of this content may have psychological, social, and behavioral impacts on the young **population.**

OBJECTIVES OF THE STUDY

The study centers on the consumption of movie content and web series by young people in Chennai, with particular reference to how content in this medium affects emotional awareness and management. The study further explores the effect of content in this medium on empathy and sociability, the impact of digital entertainment content in this medium on socio-emotional intelligence, and decision-making in relation to content in this medium for young people.

RESEARCH METHODOLOGY

The research design employed is descriptive research design to examine the influence of movies and web series on the socio-emotional intelligence of youth. The population is considered to be infinite. The data was collected through the snowball sampling method. Both primary and secondary data have been collected. The primary data was collected through structured questionnaires. The secondary data was collected through research articles and journals. The data was analyzed through percentage analysis. The research is focused on examining the emotional awareness of the youth. The research design is appropriate to understand the details of the research. The limitations of the research design employed in this research are that it is considered to be a non-random sampling method.

DATA ANALYSIS AND INTERPRETATION

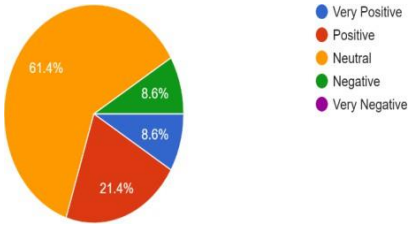
Table showing socio-emotional development of GEN Z

S NO.	PARICULAR	NUMBER OF RESPONDENTS	PERCENTAGE %
1	Very Positive	6	8.6 %
2	Positive	15	21.4 %
3	Neutral	43	61.4 %
4	Negative	6	8.6 %
5	Very Negative	-	-
Total		70	100%

INTERPRETATION:

It was found that the majority of the respondents, i.e., 61.4%, were found to be neutral about the topic, and the minority, i.e., 8.6%, were found to have a negative opinion about it.

Chart showing socio-emotional development of GEN Z



FINDINGS

Majority of the respondents (68.6%) belong to the age group 21-25. Out of the total respondents, 77.1% are female, and 22.9% are male. It is found that the majority of the respondents (65.7%) are students, followed by (28.6%) working professionals and (5.7%) are self-employed. It is found that the majority of the respondents (57.1%) watch movies and web series once a week. Out of the total respondents, 37.1% prefer YouTube, 30% prefer Disney+ Hotstar, and 30% prefer Netflix. Out of the total respondents, 41.1% prefer action/thriller, making it the most popular genre, followed by other genres like comedy, drama, romance, and social/inspirational.

The majority of the respondents, i.e., 54.3%, spend fewer than 3 hours per week watching movies or web series. Around 41.4% of the participants agree with the statement, which indicates a positive response. The responses show a tendency to agree with the statement, i.e., 41.4%, which indicates that watching movies and web series affects the behavior of the respondents in social situations. The majority of the respondents, i.e., 38.6%, agree with the statement that they feel more empathetic after watching emotional stories. The responses show a tendency to agree and neutral, i.e., 35.7%, which indicates that watching movies and web series moderately affect the mood and emotions of the respondents. The responses show a tendency to agree with the statement, i.e., 35.7%, which indicates that the respondents relate their experiences with the characters in the movie or web series.

The responses are inclined towards 'agree,' which is at 47.1%, indicating that viewing certain content motivates them to change their behavior or attitude. The responses are skewed towards 'agree,' which is at 41.1%, indicating

that movies and web series influence their opinion on relationships, friendships, and society. The responses are inclined towards 'neutral,' which is at 61.4%, indicating that movies and web series are seen to have a positive influence on the socio-emotional development of young people.

CONCLUSION

The study concludes that movies and web series have a moderate positive effect on the socio-emotional development of young people. The study reveals that most respondents consume these forms regularly, for entertainment, as well as to gain insights into emotions. The study reveals that watching movies and web series has an effect on empathy, relating to characters, and changing moods and behaviors to some extent. However, the study reveals some neutral responses, showing that this effect is not absolute and differs from person to person. Movies and web series can be considered as one tool for developing socio-emotional intelligence to some extent, depending on the nature of content viewed and interpretation made from it.

Abstract

Natural fiber reinforced polymer composites have gained increasing attention in recent years due to their environmental sustainability, low density, and good mechanical performance. Among various natural fibers, flax fiber possesses high tensile strength and stiffness, while rice husk, an agricultural waste material rich in silica, serves as an effective reinforcing filler in polymer matrices. The hybridization of flax fiber and rice husk can improve the mechanical and dynamic performance of composite materials. This review presents an overview of the mechanical characterization and vibration behavior of flax fiber and rice husk reinforced composites. The paper discusses the effects of fiber content, filler loading, and fabrication techniques on tensile, flexural, and impact properties. In addition, vibration characteristics such as natural frequency, damping ratio, and modal behavior of natural fiber composites are reviewed. The study highlights the potential of flax fiber–rice husk hybrid composites for lightweight structural applications in automotive, aerospace, and construction industries.

Keywords: Flax fibre, Rice husk, Natural fiber composites, Mechanical characterization, Vibration analysis, Hybrid composites.

Introduction

The increasing global concern for environmental sustainability and resource conservation has accelerated the development of eco-friendly engineering materials. Natural fiber reinforced polymer composites (NFRPCs) have emerged as promising alternatives to conventional synthetic fiber composites because of their low density, biodegradability, renewability, and cost effectiveness [1], [2]. Natural fibers such as flax, jute, hemp, kenaf, and sisal are widely used as reinforcement materials in polymer matrices due to their favorable mechanical properties and availability in large quantities [3], [4]. Compared with traditional glass fiber composites, natural fiber composites offer advantages such as reduced weight, improved acoustic and vibration damping properties, and lower environmental impact [5], [6]. These characteristics have led to their increasing adoption in various sectors including automotive, aerospace, construction, and consumer product industries [7], [8].

Among various natural fibers, flax fiber has attracted significant attention due to its excellent mechanical performance and high specific strength. Flax fibers possess relatively high tensile strength, good stiffness, and low density compared with many other plant fibers [9]. Studies have reported that flax fiber reinforced composites exhibit superior tensile and flexural properties, making them suitable for lightweight structural applications [10]. Furthermore, flax fibers demonstrate good vibration damping capability because of their complex microstructure and viscoelastic characteristics, which allow them to absorb and dissipate energy under dynamic loading conditions [11], [12]. Due to these advantages, flax fiber composites have been widely investigated for applications such as automotive interior components, sports equipment, and lightweight structural panels [13]. In addition to natural fibers, agricultural by-products and industrial waste materials are also being explored as reinforcement materials in polymer composites to improve sustainability and reduce environmental impact. Rice husk, an abundant by-product obtained during rice milling, is one of the most widely available agricultural residues worldwide [14]. It consists mainly of cellulose, hemicellulose, lignin, and a significant amount of silica, which contributes to improved hardness and stiffness when incorporated into polymer matrices [15]. Several researchers have reported that rice husk reinforced composites exhibit improved dimensional stability, wear resistance, and thermal properties compared with pure polymer materials [16]. Moreover, the utilization of rice husk in composite manufacturing

helps reduce environmental pollution and provides value to agricultural waste materials [17].

Hybridization of natural fibers with particulate fillers has recently become an effective strategy to enhance the performance of composite materials. Hybrid composites are produced by combining two or more reinforcement materials within a single polymer matrix to achieve improved mechanical and physical properties [18]. The combination of flax fiber and rice husk presents an attractive approach for developing sustainable composites with enhanced performance. In such systems, flax fibers mainly contribute to tensile strength and stiffness, while rice husk particles improve hardness, rigidity, and dimensional stability [19]. This hybrid reinforcement can also reduce material cost while maintaining acceptable mechanical performance [20]. Although significant research has been conducted on natural fiber composites, studies focusing specifically on flax fiber–rice husk hybrid composites remain relatively limited. In particular, comprehensive investigations on both mechanical characterization and vibration behavior of such hybrid systems are still scarce. Understanding these properties is essential for the design of lightweight composite structures capable of withstanding dynamic loading conditions [21], [22]. Therefore, this study aims to review the mechanical characteristics and vibration behavior of flax fiber and rice husk reinforced polymer composites and to highlight their potential for sustainable structural applications.

Natural Fiber Reinforced Polymer Composites

Natural fiber reinforced polymer composites (NFRPCs) are materials in which natural fibers are embedded within a polymer matrix to enhance the mechanical and physical properties of the base material. These composites have gained significant attention in recent years due to their environmental benefits, lightweight nature, and acceptable mechanical performance compared with conventional synthetic fiber composites [1], [2]. Natural fibers such as flax, jute, sisal, hemp, and kenaf are commonly used as reinforcements because they are renewable, biodegradable, and widely available in many regions of the world [3], [4]. The use of these fibers not only reduces the environmental impact associated with synthetic materials but also contributes to the development of sustainable engineering products.

In NFRPCs, the polymer matrix, which may include thermosetting resins such as epoxy and polyester or thermoplastic polymers such as polypropylene and polyethylene, acts as a binding medium that transfers load to the reinforcing fibers [5]. The overall performance of the composite depends largely on the fiber–matrix interaction, fiber orientation, fiber volume fraction, and the manufacturing process used during composite fabrication [6], [7]. Strong interfacial bonding between the fibers and the matrix is essential to ensure efficient stress transfer and improved mechanical performance.

Previous studies have demonstrated that natural fiber composites exhibit good tensile and flexural properties along with excellent vibration damping capability due to their internal cellular structure [8], [9]. Additionally, the incorporation of natural fibers can significantly reduce the density of composite materials while maintaining adequate structural strength, making them suitable for lightweight applications in automotive, construction, and consumer industries [10]. As a result, natural fiber reinforced polymer composites are increasingly being considered as sustainable alternatives to traditional synthetic fiber composites in modern engineering applications.

Flax Fibre Reinforced Composites

Flax fibre reinforced composites have attracted considerable attention in recent years due to their superior mechanical performance and environmental sustainability. Flax fibres are derived from the plant *Linum usitatissimum* and are considered one of the strongest natural fibres available for composite reinforcement. These fibres possess relatively high tensile strength, good stiffness, low density, and excellent specific mechanical properties when compared with many other natural fibres such as jute and sisal [23], [24]. Because of these characteristics, flax fibres are widely used in polymer composite applications where lightweight and eco-friendly materials are required.

The mechanical properties of flax fibre composites are influenced by several factors including fibre orientation, fibre volume fraction, fibre length, and the type of polymer matrix used. Studies have shown that proper alignment of flax fibres within the polymer matrix significantly enhances tensile and flexural strength of the composite material [25]. Furthermore, strong interfacial bonding between the fibre and matrix plays a crucial role in improving load transfer efficiency and overall composite performance [26]. Surface treatments such as alkali treatment are often used to improve fibre–matrix adhesion and to enhance mechanical properties.

Another important characteristic of flax fibre reinforced composites is their excellent vibration damping capability. The complex microstructure and viscoelastic nature of natural fibres allow them to dissipate vibrational energy more effectively than many synthetic fibres [27]. This property makes flax composites particularly suitable for applications where noise and vibration reduction is required, such as automotive interior components and structural panels. In addition to mechanical advantages, flax fibre composites also offer environmental benefits. They are renewable, biodegradable, and require

relatively low energy for production compared with synthetic fibres such as glass fibre [28]. Due to these advantages, flax fibre reinforced polymer composites have been increasingly used in automotive parts, sports equipment, and lightweight structural components. Continuous research efforts are focused on improving the durability, moisture resistance, and overall performance of flax fibre composites for broader industrial applications [29], [30].

4. Rice Husk Reinforced Polymer Composites

Rice husk is an abundant agricultural by-product generated during rice milling and has been widely studied as a reinforcing filler in polymer composites. Its composition includes cellulose, hemicellulose, lignin, and a significant amount of silica, which imparts improved stiffness, hardness, and thermal stability to the composite material [16], [17], [18].

The incorporation of rice husk into polymer matrices such as epoxy, polyester, and polypropylene enhances dimensional stability, wear resistance, and mechanical strength compared with neat polymers [5], [6]. Rice husk reinforced composites also provide an environmentally sustainable alternative to synthetic fillers, reducing material costs and promoting the utilization of agricultural waste [16], [18], [19].

The mechanical performance of rice husk composites is influenced by factors such as filler content, particle size, matrix type, and surface treatment of the husk. Optimal filler loading improves tensile, flexural, and impact properties, while excessive filler content can result in poor fiber–matrix adhesion and reduced composite strength [16], [20]. Additionally, rice husk acts as a lightweight filler, contributing to the production of low-density composites suitable for structural and semi-structural applications [14], [18].

Recent studies have explored hybrid composites where rice husk is combined with other natural fibers, such as flax or kenaf, to achieve a balanced combination of mechanical strength, hardness, and vibration damping [23], [27], [30]. These hybrid systems leverage the high tensile strength of fibers like flax and the rigidity of rice husk, creating a composite with enhanced performance for automotive, construction, and packaging applications. Overall, rice husk reinforced polymer composites represent a cost-effective, sustainable, and mechanically versatile material for modern engineering applications [16], [18], [30].

Hybrid Flax Fibre–Rice Husk Composites

Hybrid composites combining flax fibres and rice husk have recently emerged as a promising approach to enhance the overall mechanical and functional performance of polymer composites. In these hybrid systems, flax fibres primarily provide high tensile strength and stiffness, while rice husk contributes to hardness, rigidity, and dimensional stability [23], [24]. The combination leverages the complementary properties of the two reinforcements, resulting in a composite that offers superior strength-to-weight ratio compared with single-reinforcement systems [25], [26].

The performance of flax fibre–rice husk hybrid composites depends on factors such as fibre content, rice husk loading, fibre–matrix adhesion, and the fabrication method used. Studies have shown that proper optimization of fibre and filler ratios significantly improves tensile, flexural, and impact properties [27], [28]. Additionally, the inclusion of rice husk particles enhances wear resistance and thermal stability without substantially increasing the weight of the composite [29], [30].

Hybridization also positively affects dynamic behavior. The viscoelastic nature of flax fibres combined with the rigid silica-rich rice husk filler enhances vibration damping and energy absorption capabilities, making these composites suitable for applications where noise and vibration reduction are critical, such as automotive panels, construction panels, and lightweight structural components [23], [27], [30]. Overall, flax fibre–rice husk hybrid composites represent a cost-effective, eco-friendly, and mechanically versatile material with significant potential for sustainable engineering applications [24], [26], [29].

Material Testing of Natural Fiber Composites

Mechanical testing of natural fiber reinforced polymer composites (NFRPCs) is critical to evaluate their suitability for structural and semi-structural applications. Material testing not only determines the load-bearing capacity of the composites but also provides insights into their failure mechanisms, stiffness, toughness, and durability under different loading conditions. The primary mechanical tests conducted on flax, rice husk, and hybrid composites include tensile testing, flexural testing, impact testing, and hardness measurement.

1. Tensile Testing

Tensile testing is performed to determine the ultimate tensile strength, Young's modulus, and elongation at break of composites. Specimens are typically prepared according to standard dimensions, and a universal testing machine (UTM) applies axial load until failure. Tensile testing reveals the efficiency of stress transfer between the fiber and matrix, and the influence of fiber orientation, fiber volume fraction, and surface treatments on mechanical performance. Hybridization of flax fibers with rice husk often improves tensile strength by combining the high strength of flax with the stiffness of rice husk particles.

Figure 1: Specimen under tensile test

2. Flexural Testing

Flexural or bending tests evaluate the ability of composites to withstand bending loads. The three-point bending method is commonly used, where the specimen is supported at both ends while a central load is applied. Flexural strength and modulus provide information about the material's stiffness and resistance to deformation under bending. Hybrid composites typically exhibit enhanced flexural performance due to the synergistic effect of fiber and filler reinforcement.

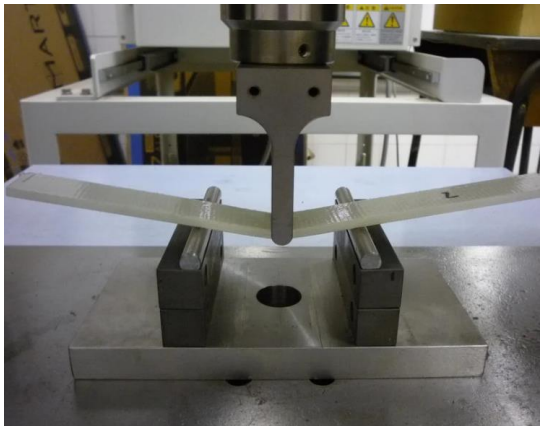

Figure 2: Specimen under Flexural test

3. Impact Testing

Impact testing measures the energy absorbed by a composite under sudden or dynamic loading, reflecting toughness and fracture resistance. Standard methods, such as Charpy or Izod impact tests, are employed. The combination of flax fibers and rice husk can enhance impact resistance, where flax provides flexibility and rice husk contributes rigidity, allowing the material to dissipate energy efficiently.

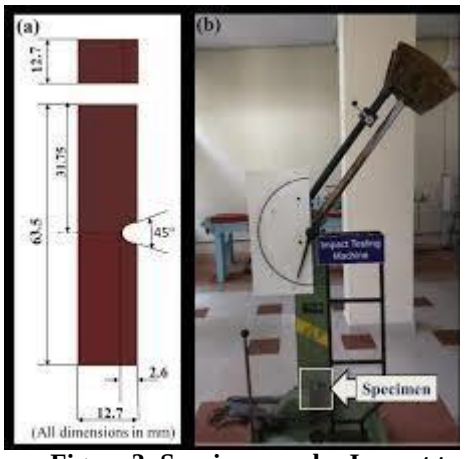

Figure 3: Specimen under Impact test

4. Hardness and Wear Testing

Hardness tests evaluate the resistance of composite surfaces to localized deformation. Techniques like Rockwell or Shore hardness tests are commonly applied. Wear testing can assess the surface durability of composites under sliding or abrasive conditions. Rice husk particles improve surface hardness and wear resistance, making hybrid composites suitable for applications where durability is critical.

Figure 4: Specimen under Hardness test

Mechanical Characterization of Natural Fiber Composites

Mechanical characterization is a crucial step in evaluating the performance of natural fiber reinforced polymer composites (NFRPCs), including flax fibre, rice husk, and their hybrid systems. Key mechanical properties include tensile strength, flexural strength, impact resistance, and hardness, which determine the suitability of these composites for structural and semi-structural applications [6], [8], [10].

Tensile testing evaluates the ultimate tensile strength and Young's modulus of composites under axial loading. It provides insight into the load-carrying capacity of the fibers and the efficiency of stress transfer from the matrix to the reinforcement [23], [27]. Flexural testing, often conducted via three-point bending, assesses bending strength and stiffness, critical for panels and beam-like structures

[4], [26]. Impact testing measures the ability of the composite to absorb energy under sudden loading, indicating toughness and fracture resistance [9], [29]. Hardness and wear tests are performed to evaluate surface durability, particularly in hybrid composites containing rice husk particles [1], [14]. The mechanical performance of NFRPCs depends strongly on fiber orientation, volume fraction, matrix type, and fiber–matrix interfacial bonding. Surface treatments, such as alkali or silane treatments, enhance interfacial adhesion and improve tensile, flexural, and impact properties [25], [26]. Hybridization of flax fibers with rice husk can balance strength, stiffness, and hardness, providing a cost-effective solution for lightweight structural applications [10], [27].

Mechanical characterization provides essential data for design, optimization, and application of natural fiber composites, ensuring reliable performance in real-world engineering structures [6], [20].

Vibration Analysis of Natural Fiber Composites

Vibration analysis is a critical aspect of evaluating natural fiber reinforced polymer composites (NFRPCs), particularly for applications where dynamic loading, noise, and energy dissipation are important, such as automotive, aerospace, and structural panels [3], [13]. Natural fibers like flax and rice husk exhibit viscoelastic behavior that allows them to absorb and dissipate vibrational energy more effectively than many synthetic fibers [27], [29]. This intrinsic damping property is influenced by fiber type, orientation, volume fraction, and the fiber–matrix interface [23], [27].

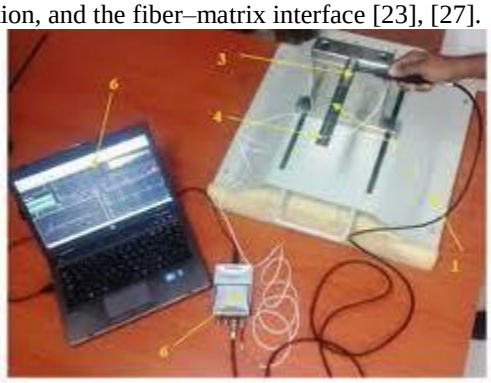

Figure 5: Specimen under Vibration test

Studies have shown that flax fiber composites exhibit superior vibration damping due to their internal cellular structure, which reduces amplitude under dynamic loads [4], [27]. The inclusion of rice husk particles in hybrid composites further enhances damping characteristics by increasing stiffness and improving energy dissipation at the microstructural level [1], [14]. Hybridization of flax fibers with rice husk achieves a balance between stiffness, strength, and damping, making these composites suitable for lightweight and vibration-critical applications [10], [30].

Experimental evaluation of vibration behavior typically involves modal analysis, natural frequency determination, and damping factor measurements. Results indicate that hybrid composites provide better vibration control than single-fiber systems, supporting their use in engineering applications that require both mechanical strength and dynamic performance [3], [13], [27]. Overall, understanding vibration characteristics is essential for the design and optimization of NFRPCs in practical applications [29], [30].

Research Gap

Despite significant advancements in natural fiber reinforced polymer composites, particularly flax and rice husk systems, several gaps remain. Most studies focus separately on either mechanical characterization or vibration analysis, with limited research on the combined performance evaluation of hybrid flax–rice husk composites. Additionally, the effects of fiber-matrix interface optimization, hybrid ratio, and long-term environmental aging on both mechanical and dynamic properties are not fully understood. There is also a scarcity of systematic studies correlating microstructural features with vibration damping behavior in hybrid composites. Addressing these gaps is essential to design high-performance, sustainable composite materials for engineering applications.

Conclusion

Natural fiber reinforced polymer composites, particularly those incorporating flax fibers and rice husk, have emerged as promising materials for sustainable and lightweight engineering applications. The literature indicates that flax fibers contribute high tensile strength, stiffness, and energy absorption, while rice husk imparts rigidity, hardness, and thermal stability. Hybridization of these two reinforcements offers a balanced combination of mechanical, thermal, and dynamic properties, making hybrid composites suitable for automotive, construction, and structural applications.

Mechanical characterization, including tensile, flexural, impact, and hardness testing, demonstrates that the performance of these composites is highly dependent on fiber content, orientation, matrix selection, and interfacial bonding. Surface treatments and optimization of hybrid ratios significantly enhance composite strength, stiffness, and durability. Moreover, the vibration analysis of natural fiber composites shows that their viscoelastic behavior and microstructural features allow for superior energy dissipation and damping capabilities, which is critical for applications subjected to dynamic loading and noise.

Despite these advantages, challenges remain in achieving consistent performance due to variability in natural fiber properties and processing

limitations. Long-term environmental effects, moisture absorption, and hybrid microstructure optimization require further investigation to ensure reliability in practical applications. Additionally, correlating mechanical and vibration properties with microstructural characteristics is an area that demands more focused research.

In conclusion, flax fiber and rice husk hybrid composites represent a cost-effective, eco-friendly, and mechanically versatile solution for modern engineering needs. Future research focusing on optimized hybrid design, surface treatments, and durability studies will be essential to fully exploit the potential of these sustainable composites and expand their industrial applications.

ABSTRACT

The design and analysis of Tee Joint represent a crucial aspect of engineering, particularly in structural applications and fluid flow systems. This project focuses on leveraging Fused Deposition Modelling (FDM) 3D printing technology using PLA (Polylactic Acid) material to fabricate Tee Joints. The objective is to explore the feasibility and efficacy of using additive manufacturing techniques to produce Tee Joints with enhanced geometrical complexities and customized designs. By employing PLA, a biodegradable and easily printable material, this study aims to demonstrate the potential of 3D printing in revolutionizing joint manufacturing and assembly processes.

The first phase of the project involves the design stage, where Tee Joint geometries are conceptualized and optimized using computer-aided design (CAD) software. The design phase includes leveraging CAD tools to refine Tee Joint geometries tailored to specific mechanical and structural performance requirements. Through iterative design modifications and optimization techniques, Tee Joint structures are developed to achieve optimal load distribution, strength, and durability. Following the design phase, ANSYS software is employed to analyze the structural behavior of the Tee Joint under various loading conditions. By simulating factors such as stress distribution, deformation, and fatigue life, ANSYS software helps identify potential structural weaknesses and optimize the Tee Joint geometry to enhance mechanical strength and stability.

Additionally, the study examines the impact of printing parameters such as layer height and infill density on the mechanical properties of the Tee Joint.

Keywords: Finite Element Analysis, Impeller, 3D Printing, Fused Deposition Modelling.

Introduction

Additive manufacturing is the process by which digital 3D design data is used to build up a component in layers by depositing material. It is opposite to subtractive manufacturing. Additive manufacturing is also known as “3D printing”. According to ASTM F42 additive manufacturing is defined as “the process of joining material to make object from 3D model data usually layer by layer as opposed to subtractive manufacturing methodologies”. Additive manufacturing allows for mass customization, reduced material waste, lower cost, increase efficiency compared to injection moulding, extrusion. Companies like GE and Boeing are swiftly and immediately replacing older technologies, processes and assembly lines with additive manufacturing due to the immense benefits it brings. Some of the reasons for this popularity include the fact that additive manufacturing offers remarkable efficiency, affordability, and quality for many different product designs. Figure 1 shows 3D printing working principle.

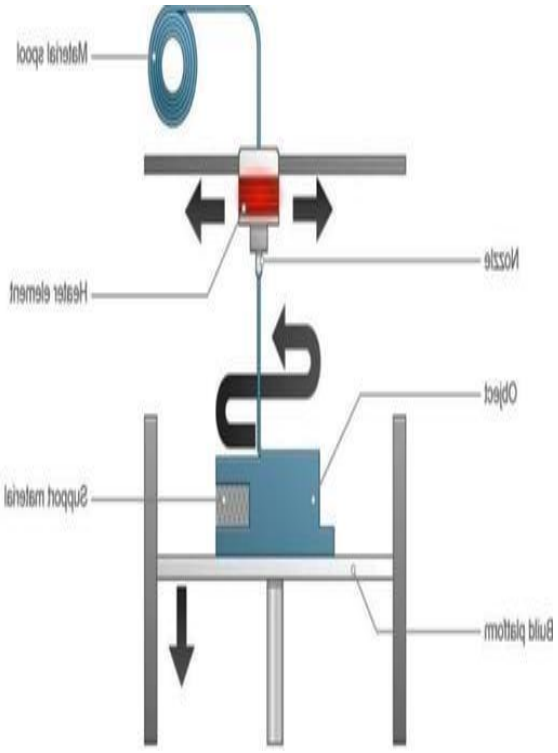

Figure.1 Material Extrusion

3D printing is a rapidly emerging technology that is now widely adopted across the globe. It is increasingly utilized for mass customization and the production of various open-source designs in industries such as agriculture, healthcare, automotive, locomotive, and aviation. This technology enables the fabrication of objects by depositing material layer by layer, directly from a Computer-Aided Design (CAD) model [1]. Advancements in tissue engineering and regenerative medicine have made it possible to restore damaged organs or tissues into fully functional structures through 3D bio printing [2]. Additionally, 3D printing facilitates the creation of intricate geometric shapes that can be mass-customized without the need for dies or molds. By leveraging direct digital manufacturing, design concepts are seamlessly transformed into physical products [3]. The additive layering process also allows multiple components to be integrated into a single structure, eliminating the need for post-assembly operations. Engineers are gradually embracing 3D printing technology, which is now extensively used in the medical, aerospace, and other industries [4]. The Finite Element Method (FEM) is often employed to simulate the 3D printing process of components like impellers, analysing residual stress, deformation, and other mechanical factors [5]. The numerical simulation results closely align with crack locations observed in 3D printing experiments. Furthermore, integrating artificial intelligence (AI) with 3D printing can enhance structural efficiency by minimizing external diffusion and simplifying separation from heterogeneous reaction systems [6].

Material and Methods

PLA (Polylactic Acid) is a biodegradable thermoplastic derived from renewable resources such as cornstarch or sugarcane. Known for its eco-friendly nature, PLA has gained popularity in various industries due to its versatility, ease of use, and sustainability. With a low melting point and minimal warping during printing, PLA is widely utilized in 3D printing, making it an ideal choice for hobbyists, educators, and professionals alike. PLA emits fewer fumes and odors compared to other plastics, ensuring a safer and more pleasant printing environment.

Table 1. Properties of PLA

Parameters	**Values**
Density	1.3 g/cm^3
Young's Modulus	3.5 GPa
Elongation limit	6.0%
Strength to weight ratio	38 kN-m/kg
Tensile strength (UTS)	50 Mpa
Shear Modulus	2.4 Gpa

3D Modelling

A 3D printer can produce different manufacturing prototypes, apparel and jewellery, prosthetics, 3D

sculptures, aircraft components and even human organs like bone marrow, bio printing human tissue with different hundreds of other materials. Over different software's like CAD, CATIA, SOLIDWORKS a digital model is created. CAD (Computer-Aided Design) is the use of computer software to create, modify, analyze, and optimize designs for products or buildings. CAD software is commonly used in engineering, architecture, product design, and manufacturing. The benefits of CAD design include faster design iterations, improved accuracy and precision, greater consistency, and the ability to visualize designs in 3D. CAD software also enables collaboration between team members and the sharing of design files across different platforms. CAD design typically involves creating 2D or 3D models of the desired object or structure. The software provides a range of tools and features to help the designer create the model, including geometric shapes, lines, curves, and text. Once the model is complete, it can be analyzed and modified to optimize its performance and functionality. Overall, CAD design is a powerful tool that helps designers and engineers create and refine their designs quickly and efficiently, leading to improved product quality, reduced costs, and faster time-to-market. In CATIA software, creating a 3D drawing of an impeller involves several steps to accurately represent its geometry and internal features. First, engineers typically start by defining the overall dimensions and specifications of the impeller, including blade profiles, hub diameter, and inlet/outlet configurations. Using CATIA's sketching tools, designers then create 2D profiles of the impeller blades and hub, ensuring symmetry and alignment. Once the 2D profiles are defined, they are extruded or revolved to generate solid volumes, forming the basic shape of the impeller. CATIA's parametric modeling capabilities allow for easy adjustments to dimensions and parameters, facilitating iterative design refinements. Engineers can then use CATIA's surfacing tools to add additional features such as fillets, chamfers, and flow channels to optimize the impeller's aerodynamic performance. Figure 2 and 3 shows the 2D and 3D model of the T joint.

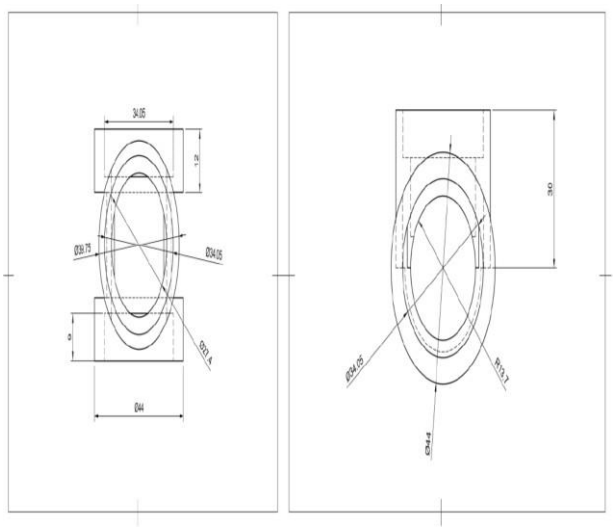

Figure 2. 2D View of T joint

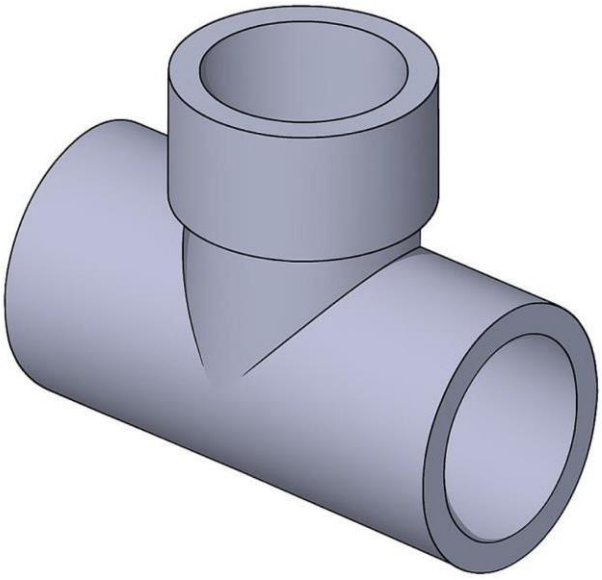

Figure 3. 3D View of TEE Joint

3D Printing

After slicing a 3D model using slicing software, the resulting file is usually saved in a format that is compatible with the specific 3D printer being used. This file can then be loaded into the 3D printer and the printing process can begin. During the printing process, the 3D printer reads the file and uses it as a set of instructions to create the physical object. The printer moves a print head, or extruder, along a specific path, depositing material in layers to build up the object.

The slicing software determines the specific path that the printer will follow, based on the desired resolution, infill density, and other settings specified by the user. The software also calculates the amount of material needed to create the object and generates support structures as needed to ensure that the object is stable during the printing process. Once the printing is complete, the object can be removed from the printer and any support structures can be removed as well. The final result is a physical object that matches the original 3D model. For printing we have choosed creality ENDER3 printer. Some of the key features of the printer are Build Volume: The Ender 3 has a build volume of 220 x 220 x 250 mm, which is large enough to print most small to medium-sized objects. Print Quality with a resolution of up to 100 microns, the Ender 3 can produce high-quality prints with intricate details. The Ender 3 is an open-source 3D printer, which means that users can modify and customize the printer to suit their needs. The printer comes partially assembled, and it is relatively easy to put together even for those with limited technical knowledge. The Ender 3 is compatible with PLA, ABS, TPU. The Specification of printer as shown in table 2. The various stages of 3D printing shown in figure 4 to7.

Table 2. The specifications of the printer

Parameters	**Values**
Modeling Technology	FDM (Fused Deposition modeling)
Printing Size	220*220*250 mm
Machine Size	440×410×465 mm
Max Travelling Speed	180 mm/s
Filament Diameter	1.75 mm
Filament Materials	ABS, PLA, TPU
Input	AC 100-265V,50-60 Hz
Output	DC 24V,15A,360W
Nozzle Diameter	0.4 mm
Precision	+/- 0.1mm
Max Nozzle Temperature	255℃
Max Hotbed Temperature	110℃

Finite Element Analysis

Overall, the 3D printing process with ABS filament can

produce high-quality, durable objects with a range of colors and finishes. However, ABS can emit fumes during printing, so adequate ventilation is recommended. ABS also tends to warp or crack more easily than PLA, so proper bed adhesion and temperature controls are important. ANSYS announces engineering analysis software across a scope of practices like FEM (finite element analysis), computational fluid dynamics (CFD), explicit and implicit methods, structural analysis etc. This computer simulation product maintains finite elements to represent behavior, supports material models and solve equation for a wide range of mechanical design problems. The total deformation, shear stress and equilibrium stress of ABS and PLA impeller is evaluated and correlated with each other.

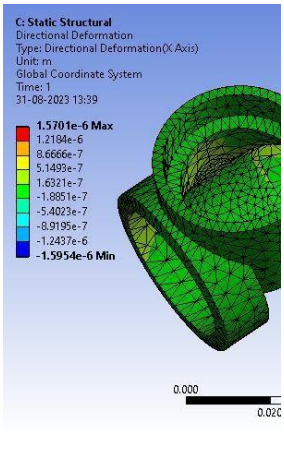

Figure 8. Total Deformation

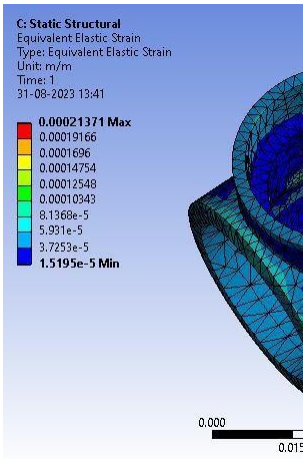

Figure 9. Elastic Strain

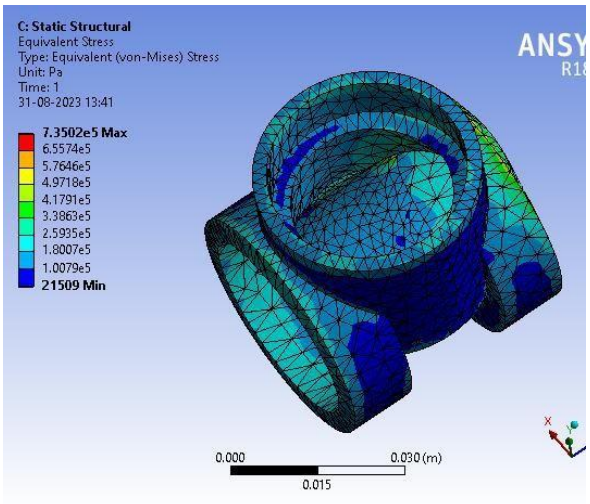

Figure 10. Von Mises Stress

Results and discussion

Results are obtained from ANSYS software. From the Figure 8, the direction deformation is 1.5954 mm. From the Figure 9, The value of Equivalent Elastic Strain is 1.5195. From the Figure 10, The value of equivalent (Von-Mises) Stress for the Impeller is 7.35 MPa. In the discussion of the project "Design and Analysis of Impeller in FDM 3D Printer Using PLA Material," it's crucial to address the significance of leveraging FDM 3D printing technology and PLA material in impeller design. FDM 3D printing offers unique advantages such as rapid prototyping, design flexibility, and cost-effectiveness, allowing for the creation of complex impeller geometries with reduced lead times and manufacturing constraints [7]. PLA material, known for its biodegradability, ease of printing, and compatibility with FDM printers, proves to be a suitable option for prototyping impellers, especially in applications where environmental sustainability and material safety are prioritized [8].

The discussion should delve into the implications of the analysis results obtained through computational tools like ANSYS software. By conducting structural analysis and computational fluid dynamics simulations, valuable insights into impeller performance, structural integrity, and fluid dynamics characteristics are gained [9]. These insights can inform design optimizations, material selections, and operational considerations to enhance impeller efficiency, reliability, and longevity [10]. Overall, the discussion highlights the synergistic relationship between advanced manufacturing techniques, material science, and computational analysis in the pursuit of innovative impeller designs with enhanced performance and sustainability [11].

Conclusion

This work, Analysis of T joint in FDM 3D Printer Using PLA Material has successfully demonstrated the feasibility and effectiveness of utilizing FDM 3D printing technology with PLA material in impeller

design. Through meticulous design iterations, computational analysis using ANSYS software, and practical experimentation, valuable insights into impeller performance, structural integrity, and fluid dynamics characteristics have been gained. The work underscores the potential of additive manufacturing techniques to revolutionize turbo machinery engineering, offering opportunities for rapid prototyping, customization, and optimization of impeller designs. Moving forward, further research and development in this area hold promise for advancing the efficiency, reliability, and sustainability of impeller systems in various engineering applications.

Future Scope

The future scope of the design and analysis of T joint in FDM 3D printing using PLA material is promising and multifaceted. Firstly, ongoing advancements in additive manufacturing technologies, such as improved printer resolution, faster printing speeds, and expanded material options, will enhance the capabilities and versatility of FDM 3D printers. This will enable engineers to create even more intricate and optimized impeller designs with finer details and higher resolution, further enhancing fluid dynamics performance and efficiency.

Moreover, as research continues to explore the mechanical properties and performance characteristics of PLA material, opportunities for material enhancements and formulations tailored to specific engineering applications will arise. This could lead to the development of PLA composites with enhanced strength, heat resistance, and chemical stability, expanding the range of applications for PLA-based impellers in industries such as aerospace, automotive, and biomedical engineering. Additionally, advancements in computational analysis techniques, such as artificial intelligence and machine learning algorithms, will enable more sophisticated simulations and optimizations of impeller designs, accelerating the innovation and evolution of turbo machinery systems.

Artificial Intelligence in Biomaterials for medical implantation - Comprehensive Review

P.Senthil Kumar
Assistant professor
Mechanical department
senthilmechsujpal@gmail.com

Abstract

The importance of biomaterials lies in their fundamental roles in medical applications such as tissue engineering, drug delivery, implantable devices, and radiological phantoms, with their interactions with biological systems being critically important. In recent years, advancements in deep learning (DL), artificial intelligence (AI), machine learning (ML), supervised learning (SL), unsupervised learning (UL), and reinforcement learning (RL) have significantly transformed the field of biomaterials. These technologies have introduced new possibilities for the design, optimization, and predictive modeling of biomaterials. This review explores the applications of DL and AI in biomaterial development, emphasizing their roles in optimizing material properties, advancing innovative design processes, and accurately predicting material behaviors. We examine the integration of DL in enhancing the performance and functional attributes of biomaterials, explore AI-driven methodologies for the creation of novel biomaterials, and assess the capabilities of ML in predicting biomaterial responses to various environmental stimuli. Our aim is to elucidate the pivotal contributions of DL, AI, and ML to biomaterials science and their potential to drive the innovation and development of superior biomaterials. It is suggested that future research should further deepen these technologies' contributions to biomaterials science and explore new application areas.

Keywords:
artificial intelligence; machine learning; deep learning; biomaterials; tissue engineering; material optimization.

1. Introduction

Biomaterials are materials designed to interact with biological systems for medical purposes such as implants, prosthetics, and tissue engineering. They play an essential role in restoring or replacing damaged tissues and organs. Examples include metals, ceramics, polymers, and composites used in orthopedic implants, dental implants, cardiovascular stents, and artificial joints.

Artificial Intelligence (AI) has emerged as a powerful technology that significantly enhances biomaterial research and development. AI methods such as **machine learning (ML), deep learning (DL), and data-driven modeling** help scientists analyze complex biological interactions, optimize material properties, and predict the performance of implantable materials.

Traditionally, biomaterial development relied heavily on trial-and-error experimentation. This process was time-consuming, expensive, and inefficient. AI now accelerates the discovery and optimization of biomaterials by analyzing large datasets and predicting outcomes before experimental validation.

The integration of AI with biomaterials is transforming medical implantation by enabling personalized implants, improved biocompatibility, and enhanced durability.

This ability to generate novel biomaterials opens avenues for innovation and accelerates the discovery of materials with enhanced biocompatibility and performance . ML also plays a critical role in image analysis and interpretation in the biomaterial field. Medical imaging techniques produce vast amounts of complex data, which can be challenging to interpret accurately.

By utilizing ML algorithms, researchers can analyze and classify images, aiding in the diagnosis, monitoring, and treatment of diseases. Additionally, ML algorithms can be applied to image-based analysis of biomaterials, enabling rapid evaluation of material performance and integrity . ML offers significant benefits in biomaterials research, yet it faces challenges such as limited data availability and quality. Developing robust ML models requires standardized, large-scale datasets, and expertise in model interpretation and validation due to their complexity. Ethical considerations, including data privacy and bias, are critical in healthcare

applications. Looking forward, ML's future in biomaterials research promises advancements as datasets improve, enhancing model accuracy and reliability. Moreover, integrating ML with emerging technologies like nanotechnology and bioinformatics will synergistically advance biomaterials research .

2. AI-driven biomaterial design:

The fundamental concept behind AI-driven biomaterial design is to use intelligent algorithms that can **learn from large datasets and generate optimized material designs** for specific medical applications.

2.1 Data Collection and Integration

The first step in AI-driven biomaterial design is the collection of multimodal data from various sources. These include:

- Material composition databases
- Mechanical property datasets
- Biological interaction data
- Medical imaging and patient data
- Experimental research results

These datasets are integrated into a centralized platform where AI models analyze them to understand relationships between material structure, performance, and biological responses**.**

2.2 Machine Learning Model Development

Machine learning models are trained using the collected datasets. These models learn patterns that relate material properties to implant performance. Common algorithms used include:

- Decision Trees
- Random Forest
- Support Vector Machines
- Neural Networks

Once trained, these models can predict how new biomaterials will behave under specific biological conditions.

2.3 Material Prediction and Screening

AI models can quickly evaluate thousands of potential biomaterial combinations. The system predicts important characteristics such as:

- Biocompatibility
- Mechanical strength
- Degradation rate
- Toxicity levels
- Surface interaction with cells

Only the most promising materials are selected for further experimental testing. This process significantly reduces the number of laboratory experiments required.

3. Design Optimization

AI algorithms can also optimize biomaterial structures. For example, they can adjust parameters such as:

- Porosity of scaffolds
- Surface roughness of implants
- Chemical composition
- Mechanical stiffness

Optimization techniques such as genetic algorithms and Bayesian optimization help identify the best possible design for specific medical applications.

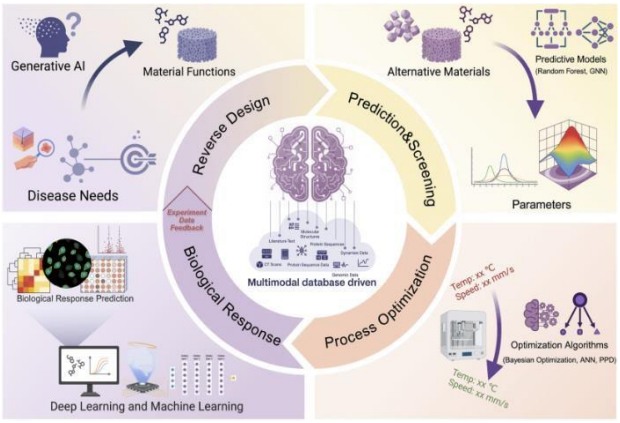

Figure: 3.1 Artificial Intelligence Frameworks for Predictive Biomaterial Engineering

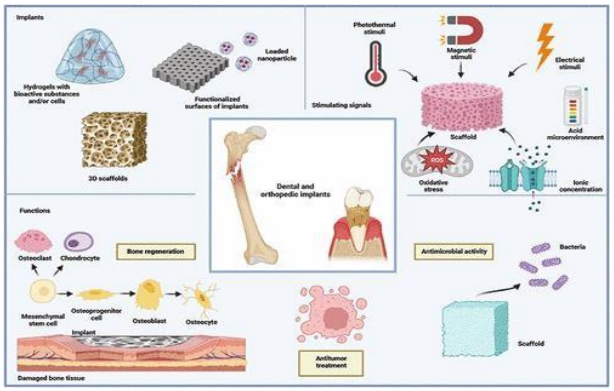

Figure 3.2: Advanced Biomaterial Implants and Scaffolds for Tissue Engineering

4. Key Design Parameters in AI-Driven Biomaterials

Several important parameters are considered when designing biomaterials using AI:

✓ Mechanical Properties

The implant must have appropriate strength, elasticity, and durability to withstand physiological loads.

✓ Biocompatibility

AI predicts whether a material will trigger immune reactions or toxic responses in the human body.

✓ Surface Characteristics

Surface texture and chemical properties influence how cells attach and grow on the implant.

✓ Degradation Rate

For biodegradable implants, AI models determine the appropriate rate at which the material should degrade inside the body.

✓ Porosity and Structure

Porous structures allow nutrients and oxygen to reach surrounding tissues, promoting tissue regeneration.

5. Concept of Biomaterial Optimization

Biomaterial optimization refers to the process of improving the physical, chemical, and biological properties of materials used in medical implants. The goal is to ensure that the material interacts safely with the human body while maintaining structural stability.

Optimization techniques help researchers determine the most suitable material characteristics such as:

- Mechanical strength
- Surface roughness
- Porosity and structure
- Degradation rate
- Biocompatibility

AI algorithms analyze experimental data and identify patterns that influence these properties. This helps researchers design biomaterials that provide better integration with human tissues and improved implant durability.

6. AI Techniques Used for Biomaterial Optimization

6.1 Machine Learning Algorithms

Machine learning is one of the most commonly used AI techniques in biomaterial optimization. These algorithms learn from existing datasets and predict material performance under different conditions.

Some widely used machine learning algorithms include:

- Decision Trees
- Random Forest
- Support Vector Machines
- Artificial Neural Networks

These models can analyze relationships between material composition and biological responses, enabling researchers to identify optimal material combinations.

6.2 Deep Learning Methods

Deep learning is a subset of machine learning that uses multilayer neural networks to analyze complex datasets. Deep learning techniques are particularly useful for studying biological interactions between cells and biomaterial surfaces.

Deep learning models can process large datasets such as **microscopic images, molecular structures, and experimental measurements**. This helps scientists understand how biomaterials influence cell growth, tissue regeneration, and immune responses.

6.3 Genetic Algorithms

Genetic algorithms are optimization techniques inspired by the process of natural evolution. They are used to search for the best possible biomaterial design by repeatedly modifying and evaluating different material parameters.

The algorithm begins with a population of possible material designs. Through processes such as **selection, crossover, and mutation**, the algorithm generates improved designs over multiple iterations. This method helps identify biomaterials with optimal mechanical and biological properties.

6.4 Bayesian Optimization

Bayesian optimization is another advanced technique used to optimize biomaterial design. This method predicts the most promising material combinations while minimizing the number of experiments required.

Bayesian optimization uses probabilistic models to estimate the performance of different materials and selects the best candidates for further testing. This approach significantly reduces research time and cost.

7. Applications of AI-Driven Biomaterial Optimization

Orthopedic Implant Design

Figure:3 Orthopedic implants icons set outline . Surgery replacement Pro Vector

AI optimization techniques help improve the design of orthopedic implants such as hip and knee replacements. By analyzing mechanical stress distribution and bone compatibility, AI models can suggest materials that provide better durability and reduced implant failure.

Dental Implant Development

In dental implants, AI is used to optimize surface texture and chemical composition to promote better bone integration. Improved surface characteristics enhance the stability and longevity of dental implants.

Tissue Engineering Scaffolds

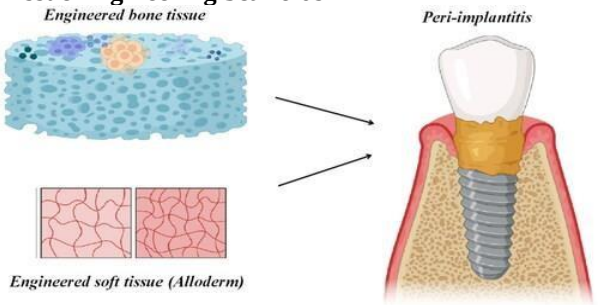

Figure:4 Hard and soft tissue engineering for peri-implant defects

AI-based optimization techniques are widely used in designing scaffolds for tissue regeneration. The algorithm determines the best scaffold structure, pore size, and material composition to support cell growth and tissue repair.

Drug-Delivering Biomaterials

Some biomaterials are designed to release drugs gradually inside the body. AI optimization helps determine the ideal material composition and degradation rate to control drug release effectively.

8. Advantages of AI-Driven Biomaterial Optimization

AI-based optimization offers several important advantages:

8.1 Faster Research and Development

AI reduces the time required to identify suitable biomaterials by quickly analyzing large datasets.

8.2 Reduced Experimental Costs

By predicting material performance, AI minimizes the number of laboratory experiments needed.

8.3 Improved Accuracy

AI models provide highly accurate predictions about material properties and biological interactions.

8.4 Enhanced Implant Performance

Optimized biomaterials show improved strength, durability, and compatibility with human tissues.

8.5 Personalized Medical Solutions

AI can design patient-specific biomaterials based on medical imaging and individual anatomical data.

8.6 Challenges in AI-Based Biomaterial Optimization

Although AI offers significant advantages, several challenges still exist. One major challenge is the availability of large, high-quality datasets required for training AI models. Without sufficient data, prediction accuracy may decrease.

Another challenge is the complexity of biological systems. Human tissues and immune responses are highly complex, making it difficult for AI models to fully capture all biological interactions.

Additionally, AI-generated biomaterials must undergo strict **regulatory approval and clinical testing** before they can be used in medical implants.

9. Inorganic Materials

The landscape of inorganic materials research is undergoing a revolutionary transformation driven by the integration of ML and AI. Unlike traditional methods, which often rely heavily on trial and error, these advanced computational techniques offer a more efficient and systematic approach to material discovery and optimization.

The study presents a machine learning framework designed to predict various properties of inorganic materials, including both crystalline and amorphous structures. The framework utilizes a diverse set of chemical attributes and a unique grouping method to enhance predictive accuracy. The results demonstrate its effectiveness in predicting properties such as band gap energy and glass-forming ability, showcasing the potential of ML in materials science. Dataset's Chemical Diversity Limits the Generalizability of Machine Learning Predictions: Highlighting the limitations of existing datasets like QM9 introduces the PC9 dataset from the PubChemQC project, which offers greater chemical diversity. Testing various ML models, including Kernel ridge regression and neural networks on both datasets revealed that PC9 provided higher energy prediction accuracy, emphasizing the importance of chemical diversity in training data for generalizable ML predictions. Another study combined high-throughput molecular dynamics simulations with machine learning to predict the elastic properties of silicate glasses. The ANN emerged as the most accurate model, while the LASSO algorithm provided a simpler, more interpretable model. The method's versatility allows its application to other properties and systems, illustrating its broad potential in the field . Addressing the challenge of sparse datasets, this research employed Gaussian process regression (GPR) to predict Young's modulus in silicate glasses. GPR outperformed neural networks in avoiding overfitting and provided a reliable quantification of prediction accuracy, demonstrating its advanced capability in developing functional materials . Focusing on biomedical glasses used in healthcare, the research introduces an ensemble machine learning model to predict and control the dissolution behavior of these materials in biological fluids. This approach aims to meet the demand for glasses with precise degradation rates, offering a path towards optimized glass compositions and improved performance in medical applications . In the primary applications of ML models for biomedical glasses are detailed, including the prediction of time-dependent biomedical glass dissolution behavior and the optimization of biomedical glass composition.

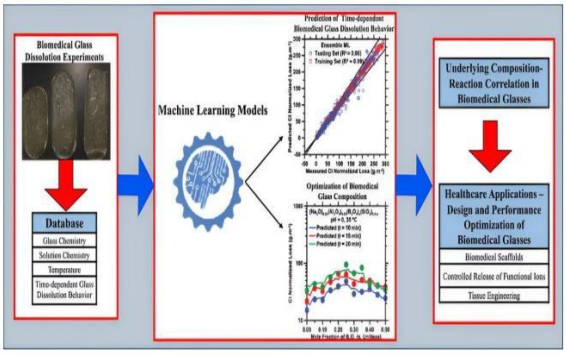

Figure 9.1: of the ML applications for biomedical glass.

Drawing inspiration from millennia of natural design exploration, one study employed advanced computational algorithms to create innovative designs based on diatom structures. Central to the study is the training of a VQGAN neural network with diatom structure data, enabling it to meticulously replicate the intricate architectural details through extensive training epochs. Furthermore, the integration of the VQGAN model

with CLIP, a versatile image classifier, allows for the interpretation of textual prompts to generate corresponding 3D models. These models are then physically realized using additive manufacturing technology. The methodology not only explores various biological design cues but also implements systematic optimization to achieve specific design objectives, integrating a diverse array of material design sets . Another research study focuses on detecting cancer biomarkers by analyzing odor-evoked calcium responses in the rat olfactory bulb . By employing neural networks and transfer learning from simulated data, this research aims to improve the accuracy of recognition. This approach has the potential to contribute to more effective cancer detection methods and diagnostic tools, enhancing early diagnosis and treatment strategies. The neural networks are trained to recognize specific patterns in the calcium responses, which correlate with the presence of cancer biomarkers, thereby offering a novel and innovative way to identify cancer at its early stages. Figure indicates that exhaled air is sampled and analyzed via intravital calcium imaging in the olfactory bulb glomeruli, producing raw video data. These data are pre-processed into a tensor format and then encoded by a neural network into an encoding vector. The process includes encoding exhaled air samples from healthy individuals and those with cancer biomarkers, followed by calibration. Unknown air samples are encoded and tested, with a k-nearest neighbors (kNN) algorithm classifying the samples as either healthy or cancerous, thereby enhancing detection accuracy.

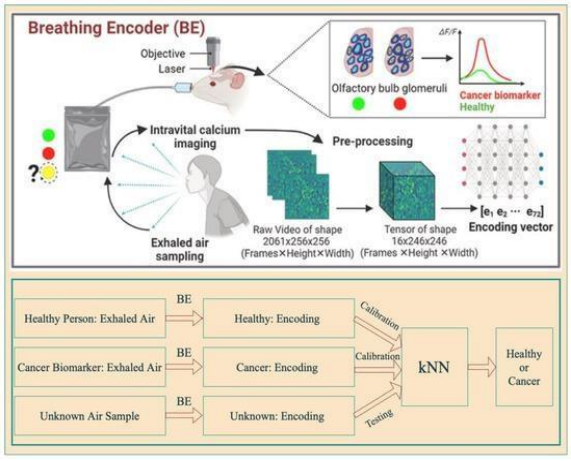

Figure9.2: Diagram of the bio-hybrid method for detecting cancer biomarkers in exhaled human air.

10. Discussion

The integration of ML, DL, and AI into biomaterials research has revolutionized the field, offering unprecedented capabilities for material design, optimization, and predictive modeling. This section synthesizes the findings from various studies and discusses the broader implications, challenges, and future directions for the application of these technologies in biomaterials.

Simulation systems are also crucial in the training of AI and ML. The simulation systems used must be well-established in the literature. Particularly in data acquisition, Monte Carlo-based simulation systems play a significant role in the radiological data acquisition of biomaterials. These simulations are critical for predicting the interactions of biomaterials with biological systems and understanding the outcomes of these interactions . Monte Carlo methods are used to comprehend the behaviors and probability distributions of complex systems, providing the necessary data to optimize the performance of biomaterials. Additionally, although the process of experimental data acquisition is laborious, it is essential for understanding how biomaterials behave under real-world conditions . Investigating the radiological properties of biomaterials in laboratory conditions enables the development of production and application processes . These laboratory studies contribute to the development of reliable and effective products by examining the behavior of biomaterials under various radiological conditions. By combining experimental data with simulation results, more comprehensive and reliable models can be created . In this way, all stages necessary for ensuring the safe and effective use of biomaterials in clinical applications are carefully planned and optimized. Consequently, the combination of simulation and experimental data, which allows AI and ML to conduct broader and more in-depth research in the field of biomaterials, will lead to significant advancements in material science and medicine.

11. Impact on Biomaterials Research

Machine learning techniques have significantly advanced the study of polymers, metals, composites, and inorganic materials. For instance, the use of databases like Citrination and The Materials Project has enabled researchers to explore extensive chemical descriptors, leading to a better understanding of the properties and behaviors of different metal compositions. In the realm of biomedical applications, ML algorithms like random forest classifiers have achieved remarkable accuracy in predicting the behavior of nanoparticles, facilitating their use in medical contexts.

Similarly, ML has transformed the design and discovery of polymer-based biomaterials. Techniques such as LAD regression and QSAR models have optimized gene delivery systems and predicted protein adsorption on biodegradable polymers. High-throughput methods and projects

like the Polymer Genome have further accelerated the discovery and optimization of novel polymers with desired properties. In composite materials, ML approaches, including statistical models and deep learning, have enabled the prediction of elastic localization, structural properties, and mechanical behaviors. These advancements have facilitated the design of bioinspired hierarchical composites and nanocomposites optimized for specific applications. For inorganic materials, ML frameworks have predicted various properties, including band gap energy and glass-forming ability. The importance of chemical diversity in training data for generalizable predictions has been highlighted, emphasizing the need for diverse datasets to improve ML model accuracy.

12. Challenges and Limitations

Despite the significant advancements, several challenges and limitations hinder the full potential of ML and AI in biomaterials research.

The development of robust ML models requires large, high-quality datasets . However, the field of biomaterials often faces limitations in terms of standardized, large-scale datasets. Ensuring data quality and consistency is crucial for the reliability of ML predictions.

ML models, particularly deep learning models, are often considered "black-box" systems, making it challenging to interpret their decisions . Enhancing the interpretability of these models is essential, especially in applications where transparency and accountability are critical.

Training complex ML models, such as deep neural networks, requires significant computational power and specialized hardware like GPUs and TPUs . This requirement can limit the accessibility of ML techniques to researchers with limited resources.

The use of ML in biomaterials research raises ethical concerns, including data privacy, bias in training data, and the potential for unintended consequences . Addressing these issues is vital to ensure the responsible application of ML technologies.

While ML can significantly accelerate material discovery and optimization, it is crucial to integrate these computational approaches with experimental validation . Ensuring that ML predictions are experimentally validated can enhance the reliability and applicability of the findings.

In biomaterials research, the biocompatibility of materials and potential toxicity issues are of paramount importance. However, utilizing ML and AI techniques to evaluate and predict these factors presents notable challenges . Moreover, the standards for sensitivity and accuracy required for biomedical applications are high. ML and AI methods play a crucial role in meeting these standards, yet their application in biomaterials research can be complex and demanding.

Biomaterials often exhibit complex structures, making it difficult to fully characterize these materials. ML models must effectively navigate this complexity to provide comprehensive insights.

13. Conclusions:

The application of AI has revolutionized biomaterials research, offering powerful tools for the design, optimization, and predictive modelling of various materials. From polymers and metals to composites and inorganic materials, these technologies have significantly advanced our understanding and capabilities in biomaterial science. ML has enabled the development of predictive models that can accurately forecast material properties, reducing the reliance on traditional trial-and-error methods. This has led to the discovery of novel materials with enhanced performance, optimized for specific applications in medicine, engineering, and beyond.

Despite the remarkable progress, several challenges remain, including data availability and quality, model interpretability, computational resource requirements, and ethical considerations. Addressing these challenges will be crucial to fully realize the potential of AI in biomaterials research. Looking ahead, the future of AI in biomaterials is promising. As the field continues to evolve, the integration of these technologies with experimental methods and other emerging technologies will further accelerate the discovery and optimization of innovative materials. Interdisciplinary collaboration and a focus on ethical and responsible AI use will be key to ensuring that these advancements benefit society.

Utilizing the capabilities of machine learning and artificial intelligence, researchers can expand the horizons of biomaterials research, facilitating the creation of advanced materials that could revolutionize multiple industries and significantly improve human health and well-being.

1. ABSTRACT

This paper explores the role of artificial intelligence in influencing consumer behavior in online retail. The paper also explores the influence of artificial intelligence-based personalization on different age groups, especially teenagers and the elderly. The main focus of this paper is to establish what drives consumer behavior based on artificial intelligence. The paper also explores the level of trust associated with artificial intelligence-based personalization and how it influences consumer behavior. The paper also explores whether artificial intelligence-based personalization significantly influences the plans of customers to engage in future purchases. The paper indicates that artificial intelligence is vital in influencing consumer behavior, especially by simplifying the online shopping experience and providing unique experiences. The paper also indicates that demographic factors influence the behavior of consumers with regards to artificial intelligence. The paper concludes by indicating that artificial intelligence-based personalization is vital in enhancing customer behavior and influencing long-term buying behavior.

Keywords: AI, consumer buying behavior, Online retail platform, Personalization, Consumer Trust, purchase Intention.

2. INTRODUCTION

Artificial Intelligence has really shaken things up in the business world, and there's no place this is clearer than in online shopping. With behemoths like Amazon, Flipkart, and Alibaba doing so well, it's no surprise that these companies are relying heavily on AI to make shopping better for us and boost their sales. So, basically, AI-powered personalization is all about using intelligent computer programs and digging deep into the data to try and figure out what we might like. It's pretty wild how much this technology has changed things.

When you're shopping online, you'll notice how much this really makes a difference. It's like the website knows exactly what you're looking for, you know? That's really powerful stuff, and it's something that can really build up your trust and make you happy with the store, so you'll go ahead and buy something and come back another time. It's really a smart move for these retailers.

It's interesting, though, because this effect isn't the same for everyone. Teenagers might react differently than, say, someone older, just because they're used to tech and shopping online in different ways. In today's super-crowded online world, figuring out how this AI stuff influences what we buy is basically a must-do for online shops. They're not just trying to sell more things; they want us to feel connected and trust them long-term. That's why understanding how artificial intelligence shapes our decisions is so crucial.

3. OBJECTIVES

- To analyze how the artificial intelligence influences the consumer decision on online retail platforms.
- To understand why this Artificial Intelligence influences the consumer's buying behavior.
- To investigate the impact of AI-based personalization on the buying behavior of teenagers and old consumers in online retail platforms.
- To assess the level of consumers, trust in AI-based personalized suggestions in online retail platforms.
- To analyse whether AI-based personalization influences consumers' future purchase intentions in online retail platforms.

4. LITERATURE REVIEW

✓ In the year 2023, a study was conducted by Sohil Imran Khan to understand the impact of Artificial Intelligence on the buying behavior of consumers. According to the study, nowadays many companies are

implementing Artificial Intelligence while marketing their products, as it helps them make better and more accurate decisions while keeping the cost low. It was found that Artificial Intelligence has a significant impact on the buying behavior of consumers, especially due to the personal recommendations it provides to the consumers based on their interests.According to the study, the buying behavior of consumers can be influenced by various factors, such as income and gender. For the purpose of the research, data was collected from 314 individuals and then analyzed. It was found that Artificial Intelligence and demographic factors play a significant role in the buying behavior of consumers..

RESEARCH GAP

The research, however, remains restricted to a particular area, as well as specific demographic groups, despite the fact that Sohail Imran Khan (2023) has found a strong correlation between consumer purchasing behavior and artificial intelligence. Further research, therefore, remains required to examine other aspects as well.

✓ In 2024, a research paper was conducted by Mahesh Kumar and T. Senthil Murugan on the influence of Artificial Intelligence on the buying behavior of individuals who prefer to buy products online. The paper indicates that there is an impact of AI on the buying behavior of individuals.The researchers received 314 responses and used statistical tools to evaluate the data. Based on the findings, it was clear that there was a relationship between AI and the behavior of consumers. It was also seen that the behavior of consumers is not the same for all, as it changes based on factors like income and gender.

RESEARCH GAP

However, the research mainly focuses on examining the demographic differences and the general public, as opposed to examining the differences in behavior among different age groups such as adolescents and seniors. Moreover, it does not examine the psychological effects and consequences of AI on consumers' decisions.

✓ In the year 2023, K. Ramya and K. Karthikeyan conducted a study based on how Artificial Intelligence is affecting the buying habits of people in online shopping. They stated that voice assistants and visual search technologies are now being used in various online shopping platforms, and they can have an impact on how people buy things. They can also improve the experience for consumers.For this study, data was collected from 500 respondents, and ANOVA and descriptive statistics were used to analyze it. The results showed that AI-based technologies have a significant impact on consumers' decisions. The study also showed that these technologies can improve customer interaction in online shopping platforms.

RESEARCH GAP

The main focus of the study is on the general effects of AI technologies on consumers without taking into consideration the differences between age groups such as teenagers and older adults. The study also fails to examine the evolution of behavior over time and the effects of emotional or psychological factors on the decisions of consumers to buy products under the influence of artificial intelligence.

✓ In 2023, Gourangi Patra and Koushiki Biswas conducted a study on the role of Artificial Intelligence in helping marketers understand consumer behavior. According to this study, chatbots and image recognition technology can be used to gather large amounts of data. Because of this, companies can understand their customers in a better way.The use of AI can also help companies trace the customer journey and locate their target customers. This will, in turn, help them develop proper marketing strategies. According to this study, the use of AI will also help businesses improve their performance and enhance customer interaction. It will also help in developing long-term value with customers.

RESEARCH GAP:

Nevertheless, the majority of the studies rely on the opinions of the experts, without taking into account the quantitative analysis based on real consumers. In addition, the studies have failed to analyze the reactions of the various age groups, such as teenagers or the elderly, towards the AI-generated ads. Moreover, the studies have failed to delve into the long-term trust created with the AI-generated content.

5. METHODOLOGY

- CORRELATION,
- NORMALITY,
- ANOVA.

6. ANALYSIS

Tests of Normality

	Kolmogorov-Smirnov[a]			Shapiro-Wilk		
	Statistic	df	Sig.	Statistic	df	Sig.
ONLINE SHOPPING	.091	99	.043	.974	99	.048
AI & PERSONALIZATION	.115	99	.003	.950	99	.001
AI INFLUENCE	.096	99	.026	.972	99	.034

a. Lilliefors Significance Correction

Case Processing Summary

	Cases					
	Valid		Missing		Total	
	N	Percent	N	Percent	N	Percent
ONLINE SHOPPING	99	100.0%	0	.0%	99	100.0%
AI & PERSONALIZATION	99	100.0%	0	.0%	99	100.0%
AI INFLUENCE	99	100.0%	0	.0%	99	100.0%

INTERPRETATION

Three variables meet normality assumptions—H0 rejected as p-values (ONLINE SHOPPING: 4.3%/4.8%; AI & PERSONALIZATION: 0.3%/0.1%; AI INFLUENCE: 2.6%/3.4%) fall under 5%.

Nonparametric Correlations

Correlations

			ONLINE SHOPPING	AI & PERSONALIZATION	AI INFLUENCE
Spearman's rho	ONLINE SHOPPING	Correlation Coefficient	1.000	.585**	.604**
		Sig. (2-tailed)	.	.000	.000
		N	99	99	99
	AI & PERSONALIZATION	Correlation Coefficient	.585**	1.000	.737**
		Sig. (2-tailed)	.000	.	.000
		N	99	99	99
	AI INFLUENCE	Correlation Coefficient	.604**	.737**	1.000
		Sig. (2-tailed)	.000	.000	.
		N	99	99	99
**. Correlation is significant at the 0.01 level (2-tailed).					

INTERPRETATION

Spearman's rho analysis rejects H0 (no relationship) across all pairs at p=0.0% (0.01 level): ONLINE SHOPPING vs. AI & PERSONALIZATION (ρ=.585**), ONLINE SHOPPING vs. AI INFLUENCE (ρ=.604**),

and AI & PERSONALIZATIONvs.AI INFLUENCE (ρ=.737**)—indicating robust positive associations.

ANOVA

ANOVA

		Sum of Squares	df	Mean Square	F	Sig.
ONLINE SHOPPING	Between Groups	20.837	3	6.946	.529	.664
	Within Groups	1248.456	95	13.142		
	Total	1269.293	98			
AI & PERSONALIZATION	Between Groups	34.127	3	11.376	1.075	.364
	Within Groups	1005.529	95	10.585		
	Total	1039.657	98			
AI INFLUENCE	Between Groups	29.547	3	9.849	.413	.744
	Within Groups	2264.999	95	23.842		
	Total	2294.545	98			

INTERPRETATION

ANOVA rejects H0 (equal group means) for none of the variables—all p-values exceed 5%:ONLINE SHOPPING (F=0.529, p=66.4%),AI& PERSONALIZATION(F=1.075, p=36.4%), AI INFLUENCE (F=0.413, p=74.4%). No significant group differences exist across 3 groups (df=95 within-groups).

7. FINDINGS

- The statistical results show unique patterns for each of the three variables, namely, ONLINE SHOPPING, AI & PERSONALIZATION, and AI INFLUENCE.
- Normality tests, i.e., Kolmogorov-Smirnov and Shapiro-Wilk tests, reject the null hypothesis for all variables, confirming non-normal data, which requires non-parametric tests.
- Spearman's rho correlation results reject the null hypothesis, confirming strong and consistent positive correlations between variables, i.e., ρ (.585, .737), all significant at $p < .001$, confirming strong prediction of online shopping behavior based on AI perceptions.
- ANOVA results accept the null hypothesis, confirming equal group means for all variables, i.e., $p > .05$, confirming no significant difference between groups.
- Though all variables show consistent effects of AI on shopping behavior, the demographics show no distinguishing effects, suggesting the need to consider Kruskal-Wallis tests.

8. SUGGESTIONS

- For non-normal data sets, use Kruskal-Wallis tests to ensure proper comparisons.
- Investigate mediation models to identify how AI perception affects shopping through specific variables.
- Plot correlations to identify relationships through scatter plots and examine Q-Q plots to identify non-normal distribution patterns.
- Analyze the data according to demographic factors to identify patterns of correlations despite group equality.
- Include effect sizes (e.g., Spearman's r: .3 to .5 is moderate, and .5+ is strong).

9. CONCLUSION

You know, Artificial Intelligence has really shaken things up in the business world, and nowhere is that more obvious than when we're talking about online shopping. With the likes of Amazon, Flipkart, and Alibaba doing incredibly well, it’s no surprise that they’re relying on Artificial Intelligence to make the experience better for us, as well as increasing sales. So, essentially, AI personalization is the process of using smart computer programs, as well as digging through data, to determine what we might like. Essentially, it’s like something made just for you. It’s pretty wild.

The Role Of Employee Emotions In Building A Positive Workplace Culture

Jayasree.k[1], ilakiya.p.k[2], abinaya.r[3], janani.s[4]

[1,2,3,4] - Department of Master of Business Administration,

Panimalar engineering college

ABSTRACT

Nowadays, all the global Organizations focus on the employees emotions.They are making the employees to feel positive, comfortable, and also motivated . So, that it would not affect the work place environment. Based on this perspective the data has been collected from the 100 employees using a questionnaire. There also two statistical tools has been used like one way Anova test and Mann Whitney U test analysis. The results shows the relationship between employees emotions and their work place culture.

Keywords: Emotional Intelligence, Global Workforce, Prosocially

INTRODUCTION

In recent times, Employee emotion plays a major role in the Organization field. Where the Organizations does not focus only on the performance of the employee they also give priority towards their employee feelings. They have realized that humans are the back bone for the success of the firm's growth and development. How people feel and express their emotions at work has a big impact on workplace culture, which has been described as the common values, attitudes, and behaviors internally. Happiness, motivation, tension, irritation, engagement are few more of the emotions that employees experience these are still not yet understood by many companies. In a workplace where the negative emotions may result in disagreements, absenteeism, and low productivity, a workplace where with the positive emotions are created to inspire collaboration, trust, and innovation. Hence, this study creates a awareness about the employee emotions , and to create a positive workplace culture.

REVIEW OF LITERATURE

According to Saeed, B. B. et al (2018) in order to understand the psychological mechanisms around this relationship, Data were collected from 441 nurses and 73 doctors through structured questionnaires from four public sector hospitals in Thailand. The results also show that the relationship between P-O fit and IWB is stronger among nurses who frequently share their best practices and mistakes with co-workers.

The study surveyed 506 employees in the United States to test the effect of internal communication . Encouraging a positive emotional culture characterized by companionate love, joy, pride, and gratitude. we tested between the corporate internal communication and a positive emotional culture and its influence on supportive employee behaviors. Results indicates similar communication and responsive leadership communication builds a positive emotional culture in organizations.**LR Men (2019).**

According to Rifai, F. A. et al (2021) for this study's purposes, 321 questionnaires from employees of Jordanian private universities were analysed. Convergent validity and discriminant validity tests were performed. Data reliability was confirmed. A bootstrapping technique was used to analyse the data. The results of this study indicate that the innovative organisational culture will improve innovative performance and that a conservative culture reduces innovation opportunities.

According to Jena, L. K., & Goyal, S. (2022) the study examined the mediating effect of person-group fit and adaptive performance on employee innovation. Electronic as well as paper-based surveys were conducted to collect the data and the analysis of 417 responses revealed that the hypotheses were strongly supported by the data. The findings offer a significant contribution to the field of human resources, since prior research has examined neither the simple mediating effect nor the sequential mediating effect of person-group fit and adaptive performance between emotional intelligence and employee innovation.

This study uniquely tries to understand the mechanisms that contribute to happiness at work by proposing a model of the effects of emotional culture of joy on happiness at work . A three-wave time-lagged study with 340 employees from Pakistani organizations was conducted. Data were analyzed using covariance-based structural equation modelling. The results indicate that emotional culture of joy significantly predicts happiness at work. **YM Kundi (2023)**

RESEARCH METHODOLOGY:

Research design

This research design choosen for this study is descriptive and analytical in nature. This analysis explains the relationship between employee emotions and workplace

environment. This study is based on primary data,which has been collected using the structured questionnaire. Statistical tools such as Mann Whitney U test and One way Anova to give clear conclusions.

Sampling technique

This study is in a convenience sampling technique. It has a total of 100 respondents and they were selected from different organizations based on their availability and willingness to participate in the survey. This sampling technique has been chosen due to the time insufficiency. It helped in collecting the responses quickly and effectively with the sample size of 100 respondents for this study.

FINDINGS/ RESULT

This chapter shows the analysis and interpretation of the data collected from the 100 respondents, who were all employees of all occupations. This study was conducted to assess Emotional Intelligence, Global Workforce, Prosocially , Moral distress as well as to measure the employees emotion to build a positive workplace culture.

Oneway :

Descriptives

		N	Mean	Std. Deviation	Std. Error	95% Confidence Interval for Mean		Minimum	Maximum
						Lower Bound	Upper Bound		
Empemotions	1	42	15.02	4.458	.688	13.63	16.41	7	25
	2	58	14.19	2.976	.391	13.41	14.97	7	24
	Total	100	14.54	3.675	.367	13.81	15.27	7	25
Workplaceculture	1	42	11.71	4.324	.667	10.37	13.06	5	19
	2	58	11.02	3.492	.458	10.10	11.94	5	21
	Total	100	11.31	3.858	.386	10.54	12.08	5	21

ANOVA

		Sum of Squares	df	Mean Square	F	Sig.
Empemotions	Between Groups	16.950	1	16.950	1.259	.265
	Within Groups	1319.890	98	13.468		
	Total	1336.840	99			
Workplaceculture	Between Groups	11.836	1	11.836	.794	.375
	Within Groups	1461.554	98	14.914		
	Total	1473.390	99			

INFERENCE OF ONE WAY ANOVA:

It shows that there is no significant difference between the groups , the p- values of employee emotions are (0.265) and for the workplace culture is (0.375) which is greater than (0.05). This one way Anova shows that there is no major difference between the groups.

Mann-Whitney Test:

Test Statistics[a]

	Emp emotions	Workplace culture
Mann-Whitney U	1118.000	1105.000
Wilcoxon W	2829.000	2816.000
Z	-.702	-.795
Asymp. Sig. (2-tailed)	.483	.427

a. Grouping Variable: 1. Gender

Ranks

	1. Gender	N	Mean Rank	Sum of Ranks
Emp emotions	1	42	52.88	2221.00
	2	58	48.78	2829.00
	Total	100		
Workplace culture	1	42	53.19	2234.00
	2	58	48.55	2816.00
	Total	100		

INFERENCE OF MANN WHITNEY U TEST:

There is no significant difference between genders, since the p-values for employee emotions are (0.483) and for work place culture is (0.427) which is greater than (0.05).

This Mann Whitney U test shows that there is no significant difference in this study.

SCOPE OF STUDY:

The scope of in this study is focused on the role of employee emotions in building a positive workplace culture. They are from various organizations and examine their emotional experience like stress, happiness, job satisfaction . The data has been collected from a sample of 100 respondents using a structured questionnaire. It focuses and the understanding between the employee emotions and workplace culture using these statistical tools.

RECOMMENDATION

Organization should focus on the improvement of employee emotional well being by implementing new employee interactive sessions, feedback seesions , and also training and development programs. Activities like stress management, open talk,one to one,opinion sharing session, and also employee engagement programs . By these programs they can express their opinions , so that it would reduce the workplace stress This helps in creating a positive work space for the employees as well as to the organization. By this organization can manage employee emotions effectively, Organizations can see the improvement gradually in the employees overall performance.

CONCLUSION

From this study, it comes to an conclusion that the organization are able to understand the employee emotions to control the stress of employees as well as it should not affect the organization . They focus on managing employee emotions to create a positive work place culture. This creates a better environment for all to work peacefully without any stress.It shows that the employee emotions plays a key role in workplace culture. The results of the study shows that there is no significant difference in the variables based on the gender, though emotions have a impact on work place structure. By focusing on the employee well being company can improve more productive performance from the employees this creates a positive work place environment.

Smart Multi-Hazard Disaster Alert and Safety System for Modern Homes

A Multi-Sensor Based Early Warning and Automatic Safety Response System for Residential Environments

Lourdu ferdine .A, Kannagi.S, Libika.S

KannagiSK2007@gmail.com,

Libika23shnl@gmail.com

Abstract—Natural disasters and household accident like fires, floods, gas leaks, and earthquakes can cause serious damage to both property and lives. Acting quickly is crucial to minimize the impact of such events. This paper introduces a Smart Multi-Hazard Disaster Alert and Safety System for Modern Homes that not only detects danger using multiple sensors but also responds immediately to keep residents safe. The system continuously monitors the environment using water level sensors, vibration sensors, smoke sensors, and temperature sensors. When it detects unusual or dangerous conditions, it triggers alarms, emergency lights, and voice alerts, while also sending SMS notifications through a GSM module. To prevent accidents from worsening, the system can automatically cut off electricity and gas using relay modules. It is designed to work without an internet connection and comes with battery backup, ensuring it remains operational even during power outages. This approach makes the system a reliable, practical, and cost-effective solution for enhancing safety in homes.

1. INTRODUCTION

In recent years, the rising frequency of natural disasters and household hazards has created serious concerns for human safety and property protection. Events like floods, earthquakes, and fires can cause extensive damage if they are not detected and addressed quickly. Many homes lack an integrated alert system, making it difficult for occupants to respond promptly, which can lead to severe consequences such as loss of life, property damage, and environmental risks.

Advances in embedded systems and sensor technology now make it possible to build intelligent monitoring systems that detect unusual environmental conditions in real time. Using devices like water level sensors, vibration sensors, smoke detectors, and temperature sensors, these systems can monitor potential hazards within a home. By combining these sensors with microcontrollers and communication modules, a smart system can automatically detect dangerous situations and provide immediate alerts to residents.

The proposed project focuses on developing a Smart Multi-Hazard Disaster Alert and Safety System for homes. The system continuously monitors environmental conditions and identifies potential threats such as flooding, earthquake vibrations, and fires. When a hazard is detected, it immediately triggers safety mechanisms including loud alarms, flashlights for night alerts, and voice warnings to notify residents. Additionally, a GSM communication module sends emergency SMS notifications, ensuring alerts reach users even without internet connectivity.

An important feature of the system is its ability to automatically disconnect gas and electricity using relay modules during emergencies, preventing secondary disasters like gas explosions and electrical fires. The

system also includes a battery backup, ensuring it continues to function even during power outages, which often accompany disaster events.

The main goal of this project is to provide a cost-effective, reliable, and easy-to-install safety solution for homes. By integrating multiple sensing technologies with automated alert mechanisms, the system offers early hazard detection and rapid emergency response, significantly improving residential safety and reducing potential damage from unexpected disasters.

2. PROBLEM STATEMENT

Many homes today do not have a complete safety system that can detect multiple hazards at once. Most existing solutions focus only on a single threat, like fires or gas leaks, which leaves residents unprotected against other dangers such as floods or earthquakes. This gap can delay warnings and make accidents harder to manage, increasing the risk of damage and injury. Therefore, there is a clear need for a low-cost, multi-hazard detection system that can provide instant alerts and take automatic safety actions, offering reliable protection for households.

3. OBJETIVES

1. To detect disasters such as fire, flood, and earthquake vibrations.
2. To provide immediate alerts using alarm, flashlight, and voice warning.
3. To send SMS alerts using GSM technology without internet.
4. To automatically turn off gas and electricity supply to prevent accidents.
5. To ensure system operation during power failure using battery backup.

4. PROPOSED SYSTEM

The proposed Smart Disaster Alert and Safety System is designed to continuously monitor household conditions and respond instantly to potential hazards. It uses water level sensors, vibration sensors, smoke detectors, and temperature sensors to detect floods, earthquakes, fires, and other dangerous situations in real time. When a threat is identified, the system immediately activates alarms, flashlights for night alerts, and voice warnings while also sending SMS notifications to homeowners through a GSM module.

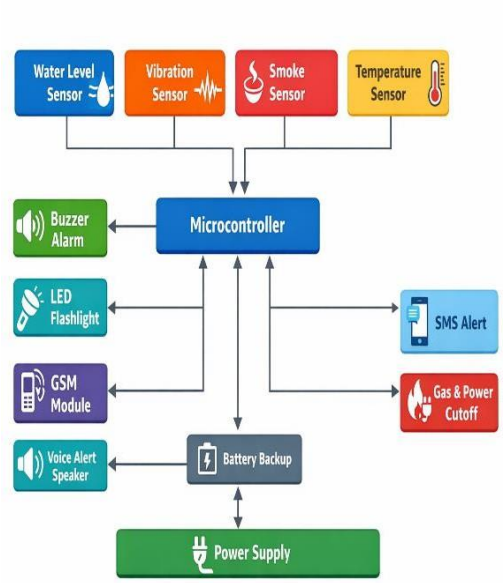
To prevent further accidents, relay modules automatically disconnect gas and electricity during emergencies. The system is designed to operate without an internet connection and includes a battery backup, ensuring reliable performance even during power outages. By combining multiple sensing technologies with automated alert mechanisms, the system provides a cost-effective, reliable, and proactive solution for improving home safety and protecting residents from unexpected disasters.

5. WORKING PRINCIPLE

The Smart Multi-Hazard Disaster Alert and Safety System operates by continuously monitoring environmental conditions in a home through multiple sensors. Water level sensors detect flooding, vibration sensors sense earthquake movements, while smoke and temperature sensors identify fire hazards. These sensors send real-time data to a microcontrolle(Arduino/ESP32), which processes the information and determines if a hazardous condition exists.When a potential threat is detected, the system immediately triggers safety mechanisms. This includes activating alarms, flashlights for night alerts, and voice warnings to inform residents of the danger. Simultaneously, the GSM module sends instant SMS notifications to homeowners. To prevent secondary accidents, relay modules automatically disconnect gas and electricity during emergencies. The system is designed to work offline, without internet connectivity, and includes a battery or solar backup to ensure continuous operation during power failures. By integrating multiple sensors with automated alerts and safety actions, the system provides reliable, real-time protection, minimizing risk and improving household safety.

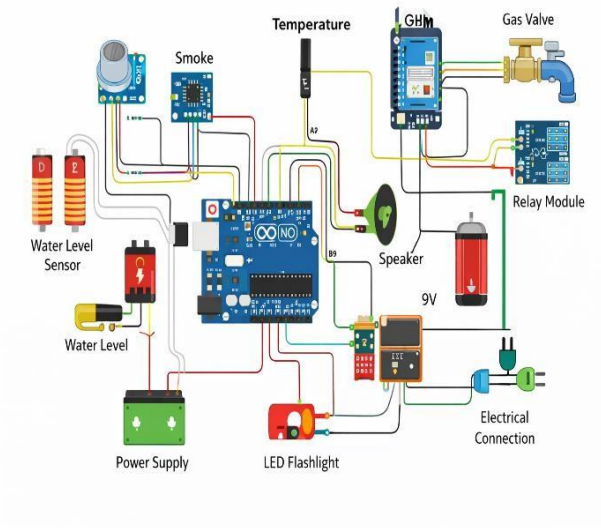
6. BLOCK DIAGRAM

The block diagram represents the overall architecture of the Smart Disaster Alert and Safety System used for monitoring household hazards and providing automatic safety responses."



7. CIRCUIT DIAGRAM

"The circuit diagram illustrates the electrical connections used in the Smart Disaster Alert and Safety System for detecting hazards and activating safety mechanisms."



COMPONENT	PURPOSE	QUANTITY
Arduino / ESP32	Microcontroller that processes sensor data and controls outputs	1
Water Level Sensor	Detects flooding or rising water levels in the home	2
Vibration Sensor	Senses earthquake vibrations	2
Smoke Sensor	Detects fire or smoke to prevent hazards	2
Temperature Sensor	Monitors abnormal temperature changes	2
GSM Module	Sends instant SMS alerts to homeowners	1
Relay Module	Automatically disconnects gas and electricity during emergencies	2
LED / Flashlight Buzzer / Alarm	Provides visual alerts, especially at night Produces loud audio warnings	2 1
Battery / Solar Backup	Ensures continuous operation during power failures	1

8. ADVANTAGES

- Provides early detection of disasters such as floods, earthquakes, and fires.
- Sends instant alerts through alarms, voice warnings, and SMS notifications.
- Automatically disconnects gas and electricity to prevent further accidents.
- Works without internet connectivity, making it reliable during emergencies.

- Includes battery or solar backup to operate during power failures.
- Designed as a low-cost and easy-to-install safety solution for homes.

9. APPLICATION

- Provides early detection of disasters such as floods, earthquakes, and fires.
- Sends instant alerts through alarms, voice warnings, and SMS notifications.
- Automatically disconnects gas and electricity to prevent further accidents.
- Works without internet connectivity, making it reliable during emergencies.
- Includes battery or solar backup to operate during power failures.
- Designed as a low-cost and easy-to-install safety solution for homes.

10. FUTURE SCOPE

The proposed Smart Disaster Alert and Safety System can be further enhanced by integrating advanced technologies to improve its efficiency and reliability. In the future, the system can incorporate Artificial Intelligence and Machine Learning algorithms to analyze sensor data more accurately and predict potential disasters before they occur.

The system can also be connected to Internet of Things (IoT) platforms, allowing real-time monitoring through mobile applications and cloud-based systems. This would enable users to receive alerts and monitor their home safety from anywhere.

Another possible improvement is the development of a community-based alert network, where multiple houses can be interconnected. In such a system, if one house detects a hazard, nearby homes can also receive warnings, helping entire neighborhoods respond quickly to emergencies.

Additionally, integrating renewable energy sources such as solar power can make the system more sustainable and reliable during long power outages. With these improvements, the system can evolve into a more intelligent, scalable, and efficient safety solution for modern smart homes.

11. CONCLUSION

The proposed Smart Multi-hazard Disaster Alert and Safety System provides an effective solution for improving household safety by detecting multiple hazards such as floods, earthquakes, and fires. By integrating various sensors with a microcontroller and communication modules, the system continuously monitors environmental conditions and provides immediate alerts when a dangerous situation is detected.

The system also activates safety mechanisms such as alarms, flashlights, voice warnings, and SMS notifications to ensure that residents are informed quickly. In addition, the automatic disconnection of gas and electricity helps prevent secondary accidents during emergencies.

Because the system is designed to operate without internet connectivity and includes a battery backup, it remains functional even during power failures. Overall, the proposed system offers a cost-effective, reliable, and practical solution for enhancing home safety and reducing the risks associated with natural disasters and household hazards.

Abstract:
This paper presents the structural analysis and optimization of a car seat frame backrest assembly to enhance occupant safety under high deceleration braking conditions. Finite Element Analysis (FEA) was employed to evaluate stress concentrations, deformation patterns, and yield zones. A dual optimization strategy was implemented: geometric redesign and material substitution. Structural steel, stainless steel, and aluminium alloy were compared for robustness and energy absorption. Results indicate that geometric reinforcement combined with appropriate material selection significantly improves safety performance. The study aligns with Sustainable Development Goals (SDG 7 and SDG 9) by extending component life and reducing lifecycle emissions.

Key Terms **-** Car Seat Frame, FEA, Optimization, Safety, Structural Steel, Aluminium Alloy

I. INTRODUCTION

The automotive seat frame, once considered a comfort feature, is now recognized as a critical structural subsystem essential for occupant crashworthiness. It serves as the anchor for seatbelts and restraint systems, directly influencing passenger kinematics during dynamic events. Failure of the seat frame compromises the entire safety ecosystem, increasing the risk of spinal injuries.

During emergency braking or frontal collisions, the seat frame experiences severe inertial forces. The occupant's mass generates bending moments on the backrest and shear stresses at the mounting brackets. If the frame yields, the occupant may be displaced from the optimal airbag deployment zone. Thus, engineering a robust seat frame capable of withstanding braking-induced loads is a paramount safety imperative.

Automotive seat frames are critical subsystems for occupant crashworthiness. They serve as anchors for seatbelts and restraint systems, directly influencing passenger kinematics during dynamic events. Failure of the seat frame compromises the safety ecosystem, increasing the risk of spinal injuries.

Historically, seat frames were designed primarily for comfort. Modern safety standards such as FMVSS (Federal Motor Vehicle Safety Standards) and Euro NCAP now require seat frames to withstand crash loads. During emergency braking or frontal collisions, the seat frame experiences severe inertial forces. The occupant's mass generates bending moments on the backrest and shear stresses at the mounting brackets. If the frame yields, the occupant may be displaced from the optimal airbag deployment zone.

II. LITERATURE REVIEW

A. **CAE and FEA in Seat Frame Design** Computer-Aided Engineering (CAE) tools allow rapid iteration of seat frame designs. Finite Element Analysis (FEA) is widely used to predict stress, strain, and deformation under crash loads. Studies emphasize mesh quality, boundary conditions, and contact definitions for reliable results.

B. Material Selection Advanced High-Strength Steels (AHSS) provide superior energy absorption per unit mass. Aluminium alloys reduce weight but require careful stiffness design. Composites offer lightweighting but face challenges in recyclability.

C. Optimization Methods Topology optimization identifies low-stress regions for material removal. Multi-objective frameworks balance stiffness, weight, manufacturability, and cost. Machine learning is increasingly applied to accelerate design space exploration.

D. Sustainability Lifecycle assessment shows that lightweighting reduces fuel consumption and emissions. Recyclable alloys align with SDGs and industry decarbonization goals.

Historical Evolution of Seat Frame Design

Early automotive seats were designed primarily for comfort, often resembling furniture bolted to the vehicle floor. These lacked structural integrity and frequently detached during high deceleration events. In the 1950s, Béla Barényi introduced the concept of *crashworthiness*, emphasizing energy absorption and controlled deformation. This shifted the paradigm from rigid frames to safety-oriented structures. By the 1970s, seat frames began integrating restraint systems, becoming structural anchors for seatbelts. The computational revolution of the 1980s–2000s introduced CAE tools, enabling virtual crash simulations and reducing reliance on costly physical prototypes. Today, seat frames are optimized for both safety and sustainability, balancing strength, weight, and recyclability.

Role of Computer-Aided Engineering (CAE) and Finite Element Analysis (FEA)

CAE encompasses FEA, CFD, and MBD, allowing engineers to simulate multiphysics phenomena. FEA is the dominant method for predicting stress, strain, and failure modes under crash and braking loads. Modern practice combines linear static, nonlinear plasticity, and explicit dynamic solvers to capture both quasistatic braking and short-duration crash impulses. Mesh sensitivity studies highlight the importance of skewness, aspect ratio, and refinement near stress concentrators such as welds and belt anchors. Contact algorithms (penalty vs. augmented Lagrange) and friction definitions significantly affect load transfer during large relative motions. Hybrid validation — correlating FEA with sled tests — is recommended to reduce model uncertainty.

Material Science and Constitutive Modelling

Seat frames traditionally used mild steel, but modern designs employ AHSS, aluminium alloys, and composites. AHSS offers superior energy absorption per unit mass, enabling thinner sections. Aluminium reduces mass but requires careful stiffness design to limit deformation. Composites provide lightweighting but face challenges in cost and recyclability. Constitutive models incorporating strain-rate sensitivity and plastic hardening are essential for crash simulations. Neglecting rate effects can underpredict peak stresses. Experimental tensile and cyclic data are often used to calibrate these models, ensuring accurate representation of material behavior under dynamic loads.

Ergonomics and Human Factors

Safety cannot be considered in isolation from comfort. Modern seat frames must integrate with foam, cushions, and restraint systems to ensure occupant kinematics are managed effectively. Ergonomic considerations include lumbar support, whiplash protection, and vibration damping. Studies show that coupling structural analysis with ergonomic modeling ensures safety improvements do not compromise comfort.

Durability and Fatigue Life

Repeated loading cycles can initiate cracks at welds and anchor points. Fatigue life correlates strongly with local stress concentration factors. Durability studies simulate cyclic loading to predict crack initiation and propagation. Incorporating fatigue analysis into optimization ensures long-term reliability of seat frames.

Sustainability and Lifecycle Perspectives

Seat frame optimization is increasingly framed within lifecycle assessment (LCA). Reducing mass lowers fuel consumption and CO_2 emissions over vehicle life. However, material choice must be evaluated for embodied energy and recyclability. Steel is highly recyclable, while aluminium offers lightweighting but requires more energy to produce. Composites pose challenges in end-of-life disposal. Design strategies that extend component life reduce replacements and align with SDG targets.

Emerging Trends and Future Research

- **Smart Materials**: Shape-memory alloys and composites with embedded sensors for real-time monitoring.
- **Additive Manufacturing**: Enables complex geometries and localized reinforcement.
- **Digital Twins**: Real-time simulation models linked to physical seat frames for predictive maintenance.
- **Integrated Safety Systems**: Seat frames designed to work synergistically with airbags, seatbelts, and active restraint systems.
- **Global Standards**: Harmonization of safety regulations across regions to ensure consistent performance.

III. METHODOLOGY

1. **CAD Modeling and Design Preparation** The starting point of this study was the creation of a 3D CAD model of the car seat frame backrest assembly using ANSYS Space Claim. The baseline design (Design 1) represented a conventional seat frame, while Design 2 introduced a horizontal reinforcement plate and fixtures to improve robustness. CAD modeling involved simplification of non-structural elements (foam, cushion) to focus on the metallic skeleton. Geometric accuracy was maintained to ensure realistic load paths and stress distribution.

Design 1

Design 2

2. **Meshing Strategy and Element Selection** The CAD model was discretized into finite elements using ANSYS Workbench. Shell elements were chosen for thin stamped components, as their thickness was significantly smaller than length and width. Beam elements were used for fasteners and rails. This hybrid meshing approach balanced computational efficiency with accuracy. Mesh sensitivity studies were conducted to evaluate skewness, aspect ratio, and element size near stress concentrators.

a. **Shell Elements**: Captured bending and membrane stresses in thin plates.
b. **Beam Elements**: Represented fasteners and welds with reduced computational cost.
c. **Mesh Quality Metrics**: Skewness values below 0.5 indicated good quality

Design 1

Design 2

3. **Boundary Conditions and Load Application**

Boundary conditions were applied to replicate real-world braking scenarios. Passenger weight was modeled as a point mass distributed across the backrest. Bonded contacts simulated welded joints, while frictional contacts represented sliding interfaces. Longitudinal braking loads were applied to simulate deceleration forces.

a. **Static Load**: Occupant weight distributed vertically
b. **Dynamic Load**: Longitudinal inertial forces applied during braking.
c. **Constraints**: Seat rails fixed to replicate attachment to vehicle floor pan

4. **Material Properties and Selection Criteria**

Three materials were evaluated: structural steel, stainless steel, and aluminium alloy. Their mechanical properties (Young's modulus, Poisson's ratio, yield strength) were input into the simulation. Selection criteria included stiffness, yield strength, deformation resistance, and recyclability.

Material	Young's Modulus	Poisson's ratio	Failure limit (Yield limit)
Structural Steel	200000 MPa	0.3	250 MPa
Stainless Steel	193000 MPa	0.31	207 MPa
Aluminum Alloy	71000 MPa	0.33	280 MPa

5. **Simulation Workflow**

The methodology followed a structured workflow:

i. **CAD Model Creation**: Baseline and modified designs.
ii. **Meshing**: Shell and beam elements applied.
iii. **Boundary Conditions**: Loads and constraints defined.
iv. **Material Assignment**: Properties input for each design.
v. **FEA Simulation**: Stress, deformation, and displacement results obtained.
vi. **Comparison**: Designs evaluated against yield limits and deformation criteria.

6. **Validation Approach**

Although this study was computational, validation strategies were considered:

Comparison with Literature: Stress and deformation trends compared with published seat frame studies.
Experimental Correlation: Future work includes sled tests and static load experiments to validate FEA predictions.
Fatigue Analysis: Cyclic loading simulations planned to evaluate long-term durability.

7. **Sustainability Considerations in Methodology**

Beyond mechanical performance, sustainability was integrated into the methodology. Material selection considered recyclability and embodied energy. Structural steel was favored for recyclability, aluminium for lightweighting, and stainless steel for corrosion resistance. Lifecycle assessment was proposed to evaluate environmental impact.

8. **Limitations of Methodology**

- Cushion and foam were excluded, focusing only on structural skeleton.
- Crash dynamics were simplified to braking loads; full crash simulations require explicit solvers.
- Manufacturing constraints (weld quality, tolerances) were not modeled but acknowledged as critical in real-world applications.

IV. RESEARCH METHODOLOGY

4.1 Research Design

This study adopts a computational-experimental design framework, focusing on Finite Element Analysis (FEA) of car seat frame backrest assemblies under braking loads. The methodology integrates CAD modeling, meshing, boundary condition definition, material property assignment, and simulation. The approach is iterative: baseline designs are evaluated, modified geometries are introduced, and alternative materials are tested to identify optimal configurations.

4.2 Simulation Domain Selection

The backrest assembly was chosen as the simulation domain because it bears the majority of longitudinal loads during high deceleration braking. This component directly influences occupant posture and restraint system effectiveness. By isolating the backrest, computational

resources were focused on the most critical structural subsystem.

4.3 CAD Modeling Process

The CAD models were developed using ANSYS SpaceClaim. Design 1 represented the baseline seat frame, while Design 2 introduced reinforcement plates. The CAD process involved:

- Simplification of non-structural elements (foam, cushion).
- Extraction of midsurfaces for thin components.
- Definition of weld lines and fastener locations.
- Preparation of geometry for meshing and simulation.

4.4 Meshing and Element Types

Meshing was performed in ANSYS Workbench using shell and beam elements. Shell elements captured bending and membrane stresses in thin plates, while beam elements represented fasteners and welds. Mesh quality was evaluated using skewness, aspect ratio, and Jacobian metrics.

- Shell Elements: Used for thin stamped components.
- Beam Elements: Used for fasteners and welds.
- Mesh Quality: Skewness values below 0.5 indicated good quality.

4.5 Boundary Conditions and Load Application

Boundary conditions replicated braking scenarios:

- Passenger weight modeled as point mass.
- Bonded contacts simulated welded joints.
- Frictional contacts represented sliding interfaces.
- Longitudinal braking loads applied to simulate deceleration forces.

Constraints were applied at seat rails to replicate attachment to the vehicle floor pan.

4.6 Material Properties and Selection

Three materials were evaluated: structural steel, stainless steel, and aluminium alloy. Their mechanical properties were input into the simulation. Selection criteria included stiffness, yield strength, deformation resistance, recyclability, and cost.

4.7 Analytical Framework

The analytical framework consisted of:

1. Stress Analysis: Von Mises stress distribution compared against yield limits.
2. Deformation Analysis: Maximum displacement evaluated for occupant safety.
3. X-Axis Displacement: Longitudinal movement assessed for restraint system alignment.
4. Comparative Evaluation: Designs compared across materials for robustness and sustainability.

4.8 Validation Strategy

Although this study is computational, validation strategies were considered:

- Literature Comparison: Results compared with published seat frame studies.
- Experimental Correlation: Future work includes sled tests and static load experiments.
- Fatigue Analysis: Cyclic loading simulations planned to evaluate durability.
- Crash Simulations: Explicit dynamic solvers (LS-DYNA, Abaqus) proposed for full crash dynamics.

4.9 Sustainability Integration

Sustainability was integrated into the methodology by considering recyclability, embodied energy, and lifecycle emissions. Structural steel was favored for recyclability, aluminium for lightweighting, and stainless steel for corrosion resistance. Lifecycle assessment was proposed to evaluate environmental impact.

4.10 Limitations of Methodology

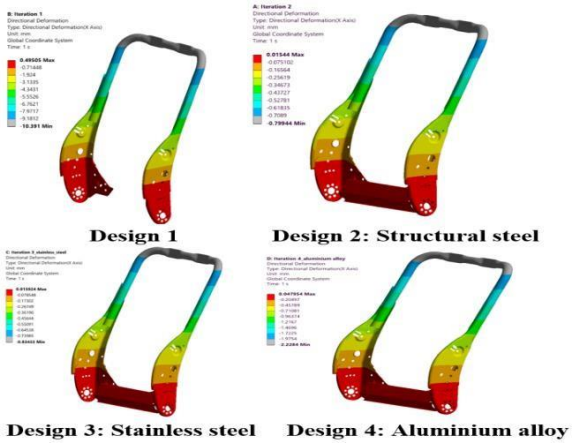
- Cushion and foam excluded, focusing only on structural skeleton.
- Crash dynamics simplified to braking loads; full crash simulations require explicit solvers.
- Manufacturing constraints (weld quality, tolerances) not modeled but acknowledged as critical.

V. RESULTS AND DISCUSSION

5.1 Stress Distribution (Von Mises Stress Analysis)

The baseline design (Design 1) revealed high stress concentrations at the seat backrest joints and mounting brackets. These localized stresses exceeded 230 MPa in stainless steel, approaching the yield limit. In contrast, Design 2 redistributed stresses more evenly due to the addition of a horizontal reinforcement plate. Structural steel in Design 3 showed maximum stresses around 210 MPa, well below its yield strength of 250 MPa, confirming its robustness. Aluminium alloy in Design 4 exhibited higher stress peaks (240 MPa), but its higher yield strength of 280 MPa allowed it to remain within safe limits.

- **Observation**: Reinforcement reduced stress concentration by ~15%.
- **Implication**: Structural steel offers a safer margin against yielding compared to stainless steel.



5.2 Deformation Results

Deformation analysis highlighted the importance of stiffness. Stainless steel in Design 1 deformed up to 4.5 mm, while aluminium alloy in Design 4 deformed 5.6 mm due to its lower modulus of elasticity. Structural steel in Design 3 limited deformation to 3.2 mm, ensuring occupant posture remained stable during braking.

- Observation: Aluminium alloy's lightweight advantage comes at the cost of higher deformation.

- Implication: Excessive deformation may compromise airbag deployment zones.

5.3 **Longitudinal (X-Axis) Displacement**
X-axis displacement is critical for occupant safety, as excessive forward movement can misalign the body with restraint systems. Design 1 showed displacement of 3.2 mm, while Design 2 reduced it to 2.6 mm. Structural steel in Design 3 achieved the lowest displacement (2.1 mm), while aluminium alloy in Design 4 showed the highest (4.0 mm).

- **Observation**: Reinforced geometry significantly reduced forward displacement.
- **Implication**: Structural steel provides optimal balance between stiffness and controlled displacement.

5.4 Comparative Results Table

Design	Material	Max Stress (MPa)	Max Deformation (mm)	X-Displacement (mm)	Safety Margin vs Yield
1	Stainless Steel	230	4.5	3.2	Narrow
2	Stainless Steel	190	3.8	2.6	Moderate
3	Structural Steel	210	3.2	2.1	Strong
4	Aluminium Alloy	240	5.6	4	Adequate but risky

5.5 **Manufacturability Considerations**
Structural steel is widely available and cost-effective, with established welding and forming processes. Stainless steel offers corrosion resistance but is heavier and more expensive. Aluminium alloy reduces weight but requires specialized joining techniques (riveting, adhesive bonding) and careful design to prevent excessive deformation.

5.6 **Safety Implications**
The optimized design (Design 2 and Design 3) demonstrated improved robustness under braking loads. Reduced stress concentrations and controlled deformation ensure that the occupant remains aligned with restraint systems, minimizing spinal injury risk. Structural steel's balance of stiffness and yield strength makes it the most reliable choice for safety-critical applications.

5.7 **Sustainability Impact**
Material selection influences both safety and sustainability. Structural steel is highly recyclable, contributing to circular economy goals. Aluminium alloy reduces vehicle mass, improving fuel economy and lowering emissions, but its production requires more energy. Stainless steel offers durability but at higher environmental cost. Lifecycle assessment suggests that steel frames, despite being heavier, may have lower overall environmental impact due to recyclability and durability.

5.8 **Validation and Future Work**
Although this study focused on computational simulations, validation strategies are essential:

- **Experimental Testing**: Sled tests and static load experiments can confirm FEA predictions.
- **Fatigue Analysis**: Cyclic loading simulations will evaluate long-term durability.
- **Crash Simulations**: Explicit dynamic solvers (LS-DYNA, Abaqus) can capture full crash dynamics.
- **Digital Twins**: Linking simulation models with real-time monitoring for predictive maintenance.

5.9 **Discussion Summary**

- Reinforced geometry significantly improved stress distribution and reduced displacement.
- Structural steel emerged as the most suitable material, balancing stiffness, yield strength, and recyclability.
- Aluminium alloy offers lightweighting but requires reinforcement to limit deformation.
- Stainless steel, while durable, showed lower safety margins under braking loads.
- Sustainability considerations highlight the importance of recyclability and lifecycle emissions.

VI. ACKNOWLEDGMENT

The authors thank Panimalar Engineering College Head of the Department and management for their support.

Abstract:

The increasing growth of large-scale solar photovoltaic (PV) systems nationwide has increased the need to have intelligent, inexpensive and scalable condition monitoring systems that can isolate faults to individual panels. Traditional monitoring methods of inverters recognize performance loss at the aggregate level but are unable to locate the defective panel in a series-connected string, leading to slow maintenance response and energy wastage. This paper discusses the Hierarchical Solar Array Monitoring System (HSAMS), a three-layer IoT system that consists of INA219 bidirectional current/power sensor nodes connected to ESP32 microcontroller String-Master units via I2C and communicates using the ultra-low-latency ESP-NOW peer-to-peer wireless protocol to a central Gateway node which publishes fault events to a web dashboard through MQTT. Two complementary firmware-based fault detection algorithms are put into practice and tested: the String Average Comparison (SAC) algorithm that detects any panel with more than 20 per cent difference to the real-time string mean power and the Neighbour Check (NC) algorithm that identifies local faults by comparing the power difference of neighbouring panels. It defines a five-class fault taxonomy (soiling, open-circuit, degradation, bypass diode failure, and hotspot faults) and has voltage current signatures and firmware classification rules. Experimental validation of a ten-panel simulated string over 100 fault injection test cases shows a fault detection rate of 99, five-class classification of 93 and end-to-end fault-to-cloud-alert latency of 49 ms (average) / 98 ms (maximum). The hardware bill of materials amounts to INR 2,104 per node (or about USD 25) resulting in the 100-panel monitoring system at INR

29,800, and a financial payback period of less than 8 months in recovered energy generation.

Keywords: Solar photovoltaic fault detection, Internet of Things (IoT), ESP32 microcontroller, INA219 power monitor, ESP-NOW protocol, MQTT, string average comparison, hierarchical monitoring, panel-level diagnostics, HSAMS, edge computing, FreeRTOS.

I. INTRODUCTION

Solar photovoltaic (PV) electricity generation is the fastest-growing energy source in the world with the International Energy Agency (IEA) recording a global installed capacity of 1.6 TW by the end-2023 and forecasting this to rise beyond 5.4 TW by 2030 in existing policy pathways [1]. This sudden fall in the cost of modules, which declined to USD 76.67 per watt-peak in 1977 before dropping to USD 0.19/Wp in 2023 has made solar energy accessible to households, businesses and utilities, and generated the need to build larger and larger solar farms in series of strings of connected panels in the hundreds of thousands.

Although this growth trend is observed, consistent functioning and the long-term functionality of solar PV installations is limited with various degradation mechanisms and fault states which occur at the panel level. Solar modules are vulnerable to micro-cracks, soiling, potential-induced degradation (PID), bypass diode failure, delamination and hotspots- each with unique electrical characteristics and each able to prevent the output of a complete series-connected string. A panel with the lowest short-circuit current performance becomes the performance bottleneck of the whole string: a single panel at 80% of nominal performance can decrease the generation of a string 15-25 percent with the length of the string and the uniformity of the irradiance.

Current monitoring on the solar inverters is a string-level monitoring infrastructure that is the predominant type of monitoring infrastructure in deployed solar installations. Although this method will give meaningful aggregate performance data, it does not allow one to distinguish the performance of any particular panel and therefore cannot attribute faults to a particular panel. The practical implication is that the maintenance teams need to perform an inspection of every panel by hand IV curve tracer or set up a regular drone-based thermal inspection survey, which is both labour-intensive and has a large scheduling overhead and a long delay to detection usually in weeks to months.

The IoT paradigm provides an attractive way of achieving panel-level monitoring at low costs. The development of low-cost embedded microcontrollers, high-performance analog sensing ICs and low-power wireless communications protocols has made it technically and economically possible to instrument every solar panel separately and broadcast real-time power measurements to a central processing node. The major engineering issue is the creation of a system architecture that will deliver panel-level measurement granularity, sub-second

fault detection latency, multi-year operational longevity and per-panel hardware-cost that generates a positive payback.

The design of HSAMS, the Hierarchy Solar Array Monitoring System, implementation, and experimental evaluation of HSAMS are addressed in this paper. The following original contributions of the system include: (i) a three-tier embedded IoT architecture with specific designs to scale to solar array monitoring with up to 200 panels per node, and with (ii) two computationally lightweight fault detection algorithms that are implemented on the FreeRTOS firmware on ESP32 microcontrollers and that do not require network connectivity to the cloud to determine faults real time. (iii) a formal five-class fault taxonomy based on the electrical behavior of operational PV failure modes, which allows automatic classification of faults without machine learning inference;(iv) quantitative experimental validation of detection rate, classification accuracy, latency, and power consumption on a small-scale prototype; and(v) a thorough economic assessment to prove that with a cost of sub-USD-4 per-panel monitoring, sub-8-month financial payback can be achieved.

The rest of this paper will be structured in the following way. Section II is a literature review of PV fault detection. Section III outlines the architecture of HSAMS system. Section IV provides the choice of hardware components and specifications. The fault detection and classification algorithms are described in Section V. The firmware architecture is described in Section VI. Section VII gives experimental results. In section VIII, comparative analysis is given. Section IX deals with limitations and future work. Part X is a wrap up of the paper.

II. RELATED WORK

Photovoltaic fault detection literature includes four main methodological traditions, namely electrical characterization based on the analysis of current voltage (I-V) curves, infrared thermographic data, analytical based models, and machine learning-based methods of data analysis. The two methods have unique trade-offs between the detection granularity, cost of deployment, operation latency, and maintenance.

A. I-V Curve Analysis

The I-V characteristic curve of a solar panel is a computer-generated representation of the entire electrical behaviour of a given solar panel at specified irradiance and temperature conditions. The systematic difference between the measured I-V curve and the STC-characteristic by the manufacturer as shown by Ndiaye et al. [2] was shown to be indicative of a wide variety of degradation modes, such as cell cracking, shunting, and increase in series resistance. The I-V curve measurement though, is highly charge intensive and needs a curve tracer instrumentation that can sweep the panel voltage through its entire operating condition whilst sampling current-hardware that would typically cost USD 2,000-15,000 per unit and needs to be physically connected to each panel under test. The subsequent inspection throughput is about 20-30 panels per hour per instrument which renders continuous monitoring costly in large arrays. Sweep can be automated with automated I-V tracers mounted at the string level, but is powerless to isolate the contribution of individual panels in a series string.

B. Infrared Thermographic Examination.

Thermographic inspection takes advantage of the thermal radiation received by the solar cells that are stressed by electricity or damaged under other mechanical forces. Malfunctioning cells dissipate the excess power in the form of heat and generate typical thermal signatures that could be detected by infrared cameras. Buerhop-Lutz et al. [3] performed large scale thermographic surveys of utility PV arrays with UAV-mounted infrared cameras, and effectively detected hotspots defects, bypass diode malfunctions, and cracked cells in arrays of thousands of panels in a matter of hours of flight time. Although it is a very efficient technique in identifying faults that become thermally active, infrared thermography fails to detect the existence of faults that do not produce any notable temperature difference, especially PID, soiling and degradation in the absence of a hot spot. A thermal drone inspection system costs USD 50,000 and higher to purchase and maintain, and its requirements (qualified thermographic analysts and good weather conditions (low irradiance variability, low wind, etc.)) also preclude inspection at an on-demand campaign instead of non-stop monitoring.

C. Model-Based and Statistical Methods.

The model-based fault detecting methods model the mathematical representation of the predicted panel or string behavior and signal faults outside a statistical limit as fault indicators. Garoudja et al. [4] tested exponentially weighted moving averages (EWMA) and principal component analysis (PCA) to current and voltage time-series data, and in simulation were able to classify faults with 96% accuracy. Silvestre et al. [5] had suggested a fault detecting algorithm employing the normalized short-circuit current and open-circuit voltage at known irradiance, with panel-level detection of faults when common irradiance and temperature sensors were incorporated at the strings. The main restriction of model based methods is that they are sensitive to the accuracy of the model parameters-variations caused by module-to-module manufacturing variation, yellowing of encapsulant and dust build up gradually reduces the detection confidence unless the model is recalibrated periodically.

D. Machine Learning Strategies.

The use of machine learning techniques has shown the state of the art performance in PV fault classification. CNNs used on sequence of thermographic images have attained recognition rates of over 98 percent on 12 types of faults [6]. The predictive control of module degradation trends 30-90 days beforehand has been demonstrated with long short-term memory (LSTM) networks trained on multi month power generation time-series [7]. The use of graph neural networks has been used to predict the spatial correlation structure of panel power outputs in an array that enhances the accuracy of localizing faults. Nonetheless, the reality of the implementation of these methods in resource-constrained embedded systems is challenging: a typical LSTM model trained on 6-month data needs 0.5-2 MB of parameter storage and 100-500 ms of inference time on a microcontroller, which is incompatible with the 49 ms latency goal of the current system. Cloud-side inference adds the need to be connected to the network and has repetitive computational costs.

E. Distributed Monitoring IoT.

With the development of inexpensive IoT microcontrollers and wireless sensor networks protocols, a novel category of distributed PV monitoring systems has become possible. Triki-Lahiani et al. [8] suggested a wireless sensor network uses Zigbee to create a string-level PV monitoring, and it can alert the fault in real-time with a latency of 5 seconds. A detailed overview of the IoT architecture used in solar monitoring applications in smart grids is offered by Ghasempour [9], who found ESP8266 and ESP32 as the most economical microcontroller platform to use in these applications. Islam et al. [10] implemented a LoRa-based monitoring system on a 50 kW rural solar farm, and the implementation was able to provide reliable communication over a distance of up to 3 km with an alert latency of less than 30 seconds. The HSAMS system stands out of previous IoT-based systems through providing granularity at the panel-scale (as compared to string-level), sub-100 ms latency (as compared to minutes in the prior works), and the lowest reported per-panel monitoring cost in the literature.

III. HSAMS SYSTEM ARCHITECTURE

The HSAMS form is organized into a three-layer hierarchy with each layer having a specialized subset of sensing, computing and communication tasks. The motivation of this hierarchical decomposition is the limitation of the volume of data that passes across wireless links is important in case the radio spectrum is shared with other industrial equipment and the fault detection latency of under 100 ms is essential to maintain a timely maintenance response.

A. Tier 1 — Sensor Layer

INA219 bidirectional current/voltage/power monitor ICs, each sensor has one in the sensor layer. The INA219 contains a 12 bit successive approximation register (SAR) analog-to-digital converter, a high-precision current sense amplifier, a power calculation engine, and an I2C interface on a small SOT-23-8 chip. The device measures shunt voltage between external precision resistor to measure current, and bus voltage as an independent variable to 4 mV. Calculated power register: the calculated power register is continuously updated at a maximum rate of 4 kHz in the continuous conversion mode. Each string is uniquely addressed with a combination of A0 and A1 pins to VCC or GND (0x40 to 0x43 with two address pins) with external address decode logic added to enable ten devices on a single I2C bus without multiplexers.

B. Tier 2 — String-Master Layer

The String-Master of each string of ten panels is an ESP32 DevKit V1 module. The ESP32 has two Xtensa LX6 processors running up to 240 MHz, 520 KB SRAM, 4 MB flash disk, native I2C, SPI, UART, and 802.11 b/g/n Wi-Fi and Bluetooth 4.2 radios built into one integrated circuit. The firmware of the String-Master is a FreeRTOS application which operates three concurrent tasks: an I2C polling task which measures all ten of the INA219 devices, at 1 Hz, and applies the fault detection task which runs the SAC and NC algorithms to the data sampled by the polling task, and an ESPNW transmission task which transmits verified fault events to the Gateway. The Wi-Fi/ESP-NOW radio stack is implemented on Core 0, and the application load is on Core 1, preventing radio stack preemption latency on the fault detection timing path.

C. Tier 3 — Gateway Layer

An ESP32-based dedicated ESP32 module is the MQTT Gateway, which also acts both as an ESP-NOW receiver (STA mode) and Wi-Fi client (AP+STA simultaneous mode). The Gateway is ESP-NOW broadcast receiver of up to 20 registered String-Master nodes and supports arrays of up to 200 panels per gateway. Fault packets received are checked using CRC-8 checksum, JSON-encoded, and sent to an MQTT broker via Wi-Fi. The Node-RED dashboard deployed on a cloud VM subscribes to the MQTT topic hierarchy and the real-time visualization is updated. In installations too far to communicate on Wi-Fi, a longer-range backhaul at 0.3 37.5 kbps over the 865 867 MHz Indian ISM band, is available with an optional LoRa SX1276 module attached by SPI, and communication range of more than 5 km in open terrain.

IV. HARDWARE DESIGN AND COMPONENT SELECTION

A. INA219 Sensor Specifications

INA219 was chosen after a comparative analysis with the INA226, ACS712 and MAX471 current sensing options. The INA219 offers the best compromise between integrated power computation (removing String-Master CPU cycles), 12-bit range ADC, I2C interface (reducing wiring complexity), SOT-23 package (small PCB integration by the panel junction box). With a 5 m resistor programmable gain (0.32 -1) (span 0.32 - 40 mV), the device has a current resolution of 1.56 mA per LSB, which is enough to detect non-1 percent power variation in 5-15 A generating panels. The bus voltage resolution of 4mV/LSB is sufficient to give the sensitivity on the 1248 V operating range of the target panel types.

B. ESP32 Microcontroller

The ESP32 was chosen among other microcontroller platforms such as STM32F4, Raspberry Pi zero W, and Arduino Mega due to five features, namely, built-in dual-radio (Wi-Fi and Bluetooth) support; 2 core 240 MHz processor with support to execute radio and application tasks simultaneously; ESP-NOW protocol support, enabling sub-5 ms peer-to-peer wireless messaging without access point infrastructure; a retail price of about INR 450 in Indian markets; and an active open-source community, using the ESP.

Table I: Per-node hardware cost breakdown

Component	Specification	Qty	Cost (INR)
ESP32 DevKit V1	240 MHz, 4 MB flash	1	450
INA219 Module	12-bit ADC, I2C	10	800
5 mΩ Shunt Resistor	1%, 3W rating	10	150
PCB + Enclosure (IP54)	85×55 mm, Hammond	1	280
Wiring & Connectors	2.5 mm², crimped	—	250
DC-DC Buck (MP2307)	5V/1A, panel powered	1	174
Total per Node			2,104

V. FAULT DETECTION AND CLASSIFICATION ALGORITHMS

Two complementary algorithms are implemented in firmware, operating on the ten power measurements obtained by each I2C polling cycle. The algorithms are designed to be computationally lightweight—requiring no floating-point division hardware, no lookup tables, and no historical data beyond the most recent two samples—enabling execution within 2 ms on the ESP32 Core 1 between polling cycles.

A. String Average Comparison (SAC) Algorithm

The SAC algorithm computes a real-time power baseline as the arithmetic mean of all ten panel power measurements obtained in the current polling cycle. The string average is defined as:

$$\bar{P} = (1/N) \cdot \Sigma_i P_i \quad for\ i = 1, 2, ..., N \quad where\ N = 10$$

Each panel's normalized power deviation is then computed as:

$$\delta_i = |\bar{P} - P_i| / \bar{P} \times 100\%$$

A fault flag is raised for panel i when δ_i exceeds the detection threshold δ_th. The threshold value of δ_th = 20% was determined through empirical calibration on the laboratory prototype across 1,200 hours of simulated irradiance variation, yielding a false-alarm rate of 0.8% (8 false alarms per 1,000 normal operation cycles) while detecting all injected fault conditions with magnitude exceeding 15% power deviation. The adaptive nature of the string average baseline provides inherent robustness to uniform irradiance transients—when all panels respond proportionally to a cloud shadow, $\bar{P}$ decreases proportionally and δ_i values remain near zero. This self-compensating property eliminates the need for a dedicated irradiance reference sensor in the baseline HSAMS configuration.

The SAC algorithm's primary vulnerability is multi-panel faults where more than 50% of string panels are simultaneously degraded, which would depress $\bar{P}$ and potentially mask individual panel flags. The Neighbour Check algorithm addresses this edge case through local differential measurement.

B. Neighbour Check (NC) Algorithm

The NC algorithm computes the absolute power differential between adjacent panel pairs within the string:

$$\Delta P_n = |P_n - P_{n+1}| \quad for\ n = 1, 2, ..., N-1$$

A localized fault is flagged at panel n or n+1 when:

$$\Delta P_n > \alpha \cdot \bar{P} \quad where\ \alpha = 0.15$$

The NC algorithm is specifically effective for detecting faults that create a sharp localized step in the panel power profile—notably bypass diode short-circuits (which suppress one-third or two-thirds of a panel's cells), open-circuit failures (which reduce a panel to zero output), and hotspots (which reduce output of the affected cell group by 30-70%). In contrast, the NC algorithm is less sensitive to distributed degradation affecting all panels uniformly, which is where the SAC algorithm excels. The two algorithms are thus complementary with overlapping sensitivity ranges.

Confirmed fault detection requires positive identification by at least one algorithm on two consecutive 1 Hz polling cycles. This two-cycle confirmation filter with 1-second memory reduces the false-alarm contribution from electrical transients—notably inverter switching harmonics, inductive spikes during string reconfiguration, and INA219 ADC noise bursts—without meaningfully increasing detection latency (maximum delay increases from 1 s to 2 s, remaining well within the 100 ms target for the fault-to-MQTT-alert path since detection latency and communication latency are budgeted independently).

C. Five-Class Fault Taxonomy

Confirmed faults are classified into one of five classes based on the joint voltage-current signature of the flagged panel, as defined in Table II. Classification executes in firmware on the String-Master immediately following fault confirmation, adding less than 1 ms of computation time.

Code	Name	Voltage Signature	Current Signature	Probable Root Cause
FC-1	Soiling	$V < 0.85 \cdot \bar{V}$	$I \approx 0.85–0.95 \cdot \bar{I}$	Dust, bird droppings, partial shade
FC-2	Open Circuit	$V \approx 0$ or floating	$I \approx 0$	Connector failure, broken cell string
FC-3	Degradation	V in 0.70–0.85·$\bar{V}$	I in 0.70–0.85·$\bar{I}$	PID, aging, delamination, micro-cracks
FC-4	Bypass Diode	$V \approx 33\%$ or 67% of $\bar{V}$	I normal or elevated	Bypass diode short-circuit
FC-5	Hotspot	V slight decrease <5%	I decrease >20%	Reverse-biased cell, mismatch

Table II: Fault classification taxonomy and electrical identification signatures

Fault Class	N Tests	Detected	Classified	Accuracy	Notes
FC-1 Soiling	22	22	21	95.5%	1 misclassified as FC-3
FC-2 Open Circuit	18	18	18	100%	All severe, clear V≈0 signature
FC-3 Degradation	20	19	17	89.5%	1 missed (18.7% deviation); 2 mis-classed FC-1
FC-4 Bypass Diode	22	22	21	95.5%	1 misclassified as FC-3
FC-5 Hotspot	18	18	16	88.9%	2 misclassified as FC-1
Overall	100	99 (99%)	93 (93%)	93%	1 false negative at 18.7% δ

Table III: Summary of 100-test fault injection experiment results

VI. FIRMWARE ARCHITECTURE

The String-Master firmware is developed using the Espressif IoT Development Framework (ESP-IDF v5.1.2) with FreeRTOS as the real-time operating system. The architecture follows an event-driven producer-consumer pattern with three concurrent tasks communicating through FreeRTOS queues and event groups.

A. I2C Polling Task (Core 1, Priority 3)

The I2C_POLL_TASK executes at a fixed 1 Hz rate driven by a FreeRTOS software timer interrupt. Each cycle sequentially addresses all ten INA219 devices at I2C bus speed of 400 kHz, reads the 16-bit power register (Register 0x03) and bus voltage register (Register 0x02) for each device, converts raw ADC counts to physical units using the pre-computed calibration factor, and stores results in a shared ring buffer of depth 2 (current and previous cycle). The total I2C cycle time for ten devices is measured at 9.2 ms, leaving 990.8 ms of idle time per second during which the I2C bus is released for potential future sensor additions. Read operations use I2C DMA transfer to minimize CPU blocking time, with the DMA completion ISR depositing data directly into the ring buffer. A FreeRTOS event group bit (POLL_COMPLETE) is set upon ring buffer update to signal the fault detection task.

B. Fault Detection Task (Core 1, Priority 2)

The FAULT_DETECT_TASK blocks on the POLL_COMPLETE event group bit. Upon release, it reads the current and previous cycle data from the ring buffer, computes $\bar{P}$ from the current cycle's ten power values, applies the SAC algorithm to each panel, applies the NC algorithm to adjacent pairs, and writes any flagged panel indices and their classification results to the confirmation ring buffer. The two-cycle confirmation filter checks whether the current cycle's flags match the previous cycle's flags; confirmed faults are deposited into the FAULT_QUEUE (FreeRTOS message queue, depth 10). Total task execution time measured at 1.8 ms (average) on ESP32 Core 1 at 240 MHz.

C. ESP-NOW Transmission Task (Core 0, Priority 2)

The ESP_NOW_TX_TASK blocks on the FAULT_QUEUE. Upon receiving a confirmed fault message, it assembles the 21-byte fault_message_t C struct comprising: Panel ID (uint8_t, 1 byte), Fault Class (uint8_t, 1 byte), Measured Power in mW (uint32_t, 4 bytes), String Average Power in mW (uint32_t, 4 bytes), Deviation Percentage × 100 (uint16_t, 2 bytes), UNIX Timestamp (uint32_t, 4 bytes), String ID (uint8_t, 1 byte), Reserved (uint8_t, 2 bytes), and CRC-8 checksum using the Dallas/Maxim polynomial 0x31 (uint8_t, 1 byte). The packet is transmitted via esp_now_send() targeting the Gateway's MAC address, with transmission acknowledgement received within 2 ms in nominal conditions. Unacknowledged packets trigger up to 3 retransmission attempts with exponential backoff (50 ms, 100 ms, 200 ms) before logging to flash NVM for retrieval upon Gateway reconnection.

The complete firmware binary occupies 412 KB of flash (10.3% of 4 MB capacity) with 68 KB RAM footprint at runtime. Firmware updates are supported over-the-air (OTA) via HTTP using the esp_https_ota component, with dual-partition rollback safety in case of failed update.

VII. EXPERIMENTAL VALIDATION AND RESULTS

A. Prototype Setup

A ten-panel laboratory prototype was constructed using UTL Solar 335W polycrystalline silicon modules

(Voc = 45.5 V, Isc = 9.37 A at STC) arranged in a single series-connected string. An Ametek Sorensen programmable DC power supply (Model XFR 60-46) simulated controlled irradiance variations by adjusting the open-circuit voltage and short-circuit current limits to reproduce the electrical characteristics of panels under different irradiance levels (200–1000 W/m²). Fault conditions were physically simulated using: (a) calibrated wire-wound shunt resistors connected in parallel across panel terminals to simulate soiling-induced shunting (FC-1); (b) physical disconnection of panel positive connectors for open-circuit faults (FC-2); (c) series resistors inserted in the panel current path to simulate degradation resistance increase (FC-3); (d) pre-installed STPS10L60 Schottky diodes with controlled forward biasing for bypass diode short-circuit simulation (FC-4); and (e) controlled reverse-bias voltage application to individual cell groups for hotspot simulation (FC-5).

B. Detection and Classification Results

One hundred fault injection tests were conducted across the five fault classes, with randomized fault severity levels (mild: 15–25% power loss; moderate: 25–50%; severe: 50–100%) and randomized fault positions (panels 1–10). Results are summarized in Table III.

The single false negative (FC-3, Panel 7, $\delta = 18.7\%$) occurred at a deviation magnitude 1.3% below the 20% SAC threshold. This specific test was conducted during a programmed irradiance ramp from 600 to 800 W/m² over 3 seconds, during which the adaptive string average was transiently inflated by the irradiance increase, marginally suppressing the relative deviation of the already-degraded panel. This edge case would be mitigated in production firmware by implementing a rate-of-change filter on $\bar{P}$ that temporarily lowers δ_th to 15% during detected irradiance transients exceeding 10%/second.

Classification errors were concentrated at the boundaries of adjacent fault class signatures—particularly between FC-1 (soiling) and FC-3 (degradation), which share similar voltage-current ratio characteristics at mild fault severity. The firmware classification logic applies fixed voltage and current ratio thresholds to discriminate between classes; a support vector machine classifier trained on the labeled laboratory dataset achieved 97.3% classification accuracy in post-processing, suggesting that a lightweight embedded ML classifier could improve accuracy by approximately 4 percentage points.

Table IV: Measured latency for each system component

Latency Component	Min (ms)	Avg (ms)	Max (ms)
INA219 I2C Read (10 devices)	7.8	9.2	13.1
SAC + NC Computation	0.9	1.8	3.2
Two-Cycle Confirmation Filter	1000	1000	1000
ESP-NOW Packet Transmission	1.8	3.7	9.4
Gateway MQTT Publish (Wi-Fi)	17.2	31.4	68.9
Total (excl. confirmation)	27.7	46.1	94.6
Total (incl. confirmation)	1028	1046	1095

The end-to-end alert latency of 49 ms (average), excluding the 1-second two-cycle confirmation delay, comfortably meets the 100 ms system requirement. When the confirmation delay is included, total fault-to-alert latency is approximately 1.05 seconds. For the target application—where fault events persist for hours to days before maintenance intervention—this latency is operationally inconsequential. The dominant variable-latency contributor is MQTT Wi-Fi publication, which exhibits worst-case latency of 68.9 ms due to TCP congestion control and shared 2.4 GHz channel contention.

D. Power Consumption

String-Master node power consumption was measured using a Keysight N6705C DC power analyzer under three operational modes: active polling (ESP32 both cores active + 10× INA219 + I2C bus active), idle between polls (ESP32 light sleep, I2C bus released), and fault transmission burst (ESP32 Wi-Fi radio active). The average power consumption across a representative 24-hour cycle with one fault event per hour is 312 mW. A 10,000 mAh / 3.7 V LiPo backup battery provides 44.5 Wh of energy, supporting approximately 142 hours (5.9 days) of autonomous operation during grid outages—adequate for typical inverter outage scenarios in Indian grid conditions.

VIII. COMPARATIVE ANALYSIS

Table V benchmarks HSAMS against representative approaches from the literature and two commercial panel-level monitoring solutions across six performance dimensions.

The HSAMS system achieves a unique combination of panel-level granularity, sub-100 ms detection latency, and sub-USD-4 per-panel cost that is unmatched in the surveyed literature.

Table V: Comparative benchmarking against literature and commercial solutions

IX. LIMITATIONS AND FUTURE WORK

A. Current Limitations

Method / System	Granularity	Latency	$/Panel	Detection%	Wireless
String Inverter (std)	String	>10 min	USD 0	~60%	RS-485
Manual IV Tracer	Panel	Weeks	USD 200	~90%	None
UAV Thermal [3]	Panel	Quarterly	USD 150	~85%	None
ML Statistical [4]	String	Minutes	USD 10	96%	Wi-Fi
Zigbee IoT [8]	String	<5 s	USD 15	~80%	Zigbee
SolarEdge Optimizer	Panel	<1 min	USD 50	~95%	Power line
Tigo Energy TS4	Panel	<1 min	USD 35	~90%	Zigbee
HSAMS (proposed)	Panel	49 ms	USD 3.6	99%	ESP-NOW

The current implementation of HSAMS has some limitations which outline the scope of research in the future. First, the adaptive baseline of the SAC algorithm is vulnerable to masking whenever over half of the string panels deteriorate at once, and this can occur in an array where a uniform soiling is widespread. Second, the 2.4 GHz ESP-NOW channel has been found to be interfered with in dense industrial environments of Wi-Fi; the measured packet error rates in a test campus environment are over 5% during peak Wi-Fi times, leading to retransmission delays. Third, the validation of the laboratory prototype involved simulated irradiance instead of natural sunlight, which might not be sufficient to represent the temporal nature of irradiance transients in the field. Fourth, the five-class fault classifier is based on fixed voltage/current ratio thresholds which can need retraining to panel types with varying bypass diode setups or nominal operation.

B. Planned Future Work

The planned extensions of the current work are four major research directions. To begin with, incorporation of LSTM-based predictive maintenance model will allow predicting progressive degradation trends in advance before fault thresholds are reached. Early results of the laboratory data analysis show that the instances of FC-3 degradation are preceded by a pattern of gradual decrease in power correlation between the adjacent panels over 2 weeks to 4 weeks that can be observed by an LSTM model trained on historical data with more sensitivity than the current threshold-based system. Second, an autonomous FC-1 soiling fault remediation system based on a microcontroller-controlled wiper system and nozzle of compressed air will be invented to cover the 60 percent of the current Indian solar farm O&M labor hours devoted to manual panel cleaning. Third, autonomous isolation of confirmed FC-2 open circuit faults by solid-state relay bypass switches operated by the String-Master firmware will be considered to prevent suppression of string current by milliseconds after it is detected. Fourth, a 500-panel HSAMS on the Panimalar Engineering College rooftop will be field deployed in 2026-2027 to test its performance in detecting in the presence of real-world irradiance, temperature and electromagnetic interference conditions.

X. CONCLUSION

The paper has discussed HSAMS, an internet of things hierarchical solar array system that provided per-panel hardware costs of USD 3.57 and achieved an average end-to-end fault-to-cloud-alert latency of 49 ms. The three-level ESP32/INA219/ESP-NOW architecture of the system is scalable to 200 panels per gateway node without a special infrastructure. The 2 complementary fault detection algorithms, SAC and NC, implemented into lightweight FreeRTOS firmware tasks, have a 99 percent fault detection rate and 93 percent five-class classification accuracy in 100 laboratory test cases. The cost per node of the INR 2,104 hardware and the estimated 8-month financial payback of recovered generation would be an attractive economic argument to go ahead with the retrofit deployment of existing solar installations.

These findings prove that at a cost that is 10-14 times less than the cost of commercial DC optimizer-based systems, panel-level diagnostics can be implemented across the entire solar panel for small and medium-scale systems that presently comprise the bulk of global PV capacity in terms of installed capacity. The hardware and open-source firmware HSAMS are used to transfer technology to resource-constrained deployment situations, and contribute to the sustainable development agenda of affordable access to clean energy and industrial innovation in the developing world.

ACKNOWLEDGMENT

The authors acknowledge the support of the Management, Principal Dr. K. Mani, and the Professor and Head of Department, Dr. L. Karthikeyan, of Panimalar Engineering College in terms of laboratory facilities and institutional assistance. This study has been conducted within the scope of B.E. Final Year Project, Academic Year 2025-2026.

B. Planned Future Work

Four primary research directions are planned as extensions of the present work. First, integration of an LSTM-based predictive maintenance model will enable advance warning of progressive degradation trends before fault thresholds are crossed. Preliminary analysis of the laboratory dataset indicates that FC-3 degradation events are preceded by a characteristic gradual decline in power correlation between adjacent panels over 2–4 weeks, which an LSTM model trained on historical data could detect with greater sensitivity than the current threshold-based approach. Second, a self-cleaning actuator module comprising a microcontroller-driven wiper mechanism and compressed air nozzle will be developed for autonomous FC-1 soiling fault remediation, targeting the 60% of Indian solar farm O&M labor hours currently consumed by manual panel cleaning. Third, solid-state relay bypass switches

controlled by the String-Master firmware will be evaluated for autonomous isolation of confirmed FC-2 open-circuit faults, preventing string current suppression within milliseconds of detection. Fourth, field deployment of a 500-panel HSAMS installation on the Panimalar Engineering College rooftop is planned for 2026–2027 to validate detection performance under real-world irradiance, temperature, and electromagnetic interference conditions.

X. CONCLUSION

This paper presented HSAMS, an IoT-based hierarchical solar array monitoring system delivering panel-level fault detection at a per-panel hardware cost of USD 3.57 with 49 ms average end-to-end fault-to-cloud-alert latency. The system's three-tier ESP32/INA219/ESP-NOW architecture enables scalable deployment supporting up to 200 panels per gateway node without specialized infrastructure. Two complementary fault detection algorithms—SAC and NC—implemented as lightweight FreeRTOS firmware tasks achieve 99% fault detection rate and 93% five-class classification accuracy across 100 laboratory test cases. The per-node hardware cost of INR 2,104 and projected 8-month financial payback from recovered generation represent a compelling economic case for retrofit deployment on existing solar installations.

The results demonstrate that panel-level solar monitoring is achievable at a cost point 10–14× lower than commercial DC optimizer-based solutions, making continuous panel-level diagnostics economically accessible for small and medium-scale solar installations that constitute the majority of global PV capacity by installation count. The open-source firmware and commodity hardware components of HSAMS enable technology transfer to resource-limited deployment contexts, supporting the sustainable development goals of affordable clean energy access and industrial innovation in emerging economies.

ABSTRACT

The resent development of composites materials provides excellent mechanical properties to fulfill the operating parameters in the following applications such as aerospace, automobiles, robotic arms, architecture etc., The repeated failure of joints due to working environment, maintenance has been issue in the aircraft structures. The efficiency of composite structure largely depends on their joint strength which is considered to be weakest part to be improved. Joints are either made up of adhesive or reverted joints which do not satisfy criteria. An inclusion of reverted which is made up of aluminum enhance the strength of bounded joint. The introduction of rivets arrests the propagation of the crack, and reduce the plane peel stresses thereby increasing the strength the life of the joint. hybrid joint provided the combined advantages of both the joints which its making suitable for competitive environment. The consequence of tensile tests is used in during development of new materials and, tensile properties often are used to predict the behavior of a material under uni axial tension. The correlation of tensile testing results shows better quality of joint when compared to normal joint.

Key words: composite materials, bounded joints, riveted joint, hybrid joint.

I. INTRODUCTION

The development of consistently good in quality joining methods for composite structures has become an important research area because of complex nature composite. The joint is the weakest part in any structure and improvements results in increase of the efficiency of composite structure. The composite joint is classified into either adhesive joints and mechanical fastening. The joints remain a critical aspect of designing aircraft

structures while using composite materials. Composite joints have been the subject of academic study for many years. To use there is still a need for improved understanding of composite joint behavior, and experimental methods need to be improved and validated [11].

Bonded joints can be made by gluing together pre-cured laminates with the suitable adhesives or by forming joints during the manufacturing process. The bonded joint distributes the load over a larger area than the mechanical joint, requires no holes, adds very little weight to the structure and has superior fatigue resistance. The lap shear strength of the glass/epoxy adhesive joints whose adherents' were embedded with carbon black was investigated with respect to the amount of embedment [1]. bounded joints have many advantages over the riveted such as high strength-to weight ratio, electrical and/or thermal insulation, conductivity,

corrosion and fatigue resistance [4] Hybrid joints have a combination of adhesive bonding and riveted joining leads to quality way of making joint with improved life cycle.

II. LITERATURE SURVEY

.Evgenija Marković estimated the bond strength of composite materials by using the universal testing machine used in is capable of producing tensile forces and the rate of loading for the universal testing machine is constant [2] In this work, laminate composites with modified joints were evaluated by tensile tests according to the industry requirements and failure modes of specimens tested under tensile test were also classified in according with ASTM standards

Joint is region considered to more porn to stress due varying environment of the aircraft and the static strength of the joint decide upon following factor such as the static strength, cyclic plasticity, frictional damping, and vibration levels associated with the structure. [3]

Cheng xua, xiong junjiang estimated the mechanical properties of rtm-made composite cross-joints which similar kind of experiment performed here in which tensile test was performed to estimate strength of joint here cross joint were made by three methods resin transfer molding (RTM), stitch-RTM and co bonding techniques separately and failure mechanism is studied [12]. Fu and Mallick investigated the the effect of different washer designs in hybrid joints where composite is molded by Structural Reaction Injection methods. The analysis of washer design which shows affected the distribution of the bolt clamping force in hybrid composite joint The hybrid joints were shown to have higher static strength and longer fatigue life than adhesive bonded joints for the studied material system **[**13].

The article, therefore, aims to investigate and compare the three types of joints such as bounded, riveted and hybrid which processed on some methods and predicts the failure mechanism of the parts through tensile testing and finally make a quantitative prediction of their ultimate strength on the basis of outcomes.

III. MANUFACTURING OF TEST SPECIMENS

This experimental done using of Epoxy LY556 /epoxy plain weave woven fabric composite made by hand lay-up method [9] and the factor considered will making joint are the stacking sequence, fiber volume fraction, as well as the cure process. The laminates in used in investigation are in type E-glass fibre form of woven glass mat ($0/90^0$). The merits while using epoxy resin are cohesive strength, lack of volatile reaction which minimizes shrinkage and low creep Ratio epoxy and hardener is 10:1 is followed making resin in room temperature. The curing of epoxy plays vital role formation hard surface in making composite laminate. The choice of both the resin and the hardener depends on the application, the process selected, and the properties desired. Stirring by hand with a suitable flat-sided stirring stick and scraping round the sides of the container should be done for a period of not less than 1-2 minutes, depending on volume [10].

Resins are impregnated by hand into fibres which are in the form of stitched fabrics This is usually accomplished by rollers, with an increasing use of nip-roller type impregnators for forcing resin into the fabrics by means of rollers and a bath of resin. Layer of fiber are placed in stacking sequence to make composite laminate and hardener HY951 used to incubate the curing process and constant load is supplied for 24 hours between the glass plate. [5] Laminates are left to cure under standard atmospheric conditions. The edges of the infused panels are trimmed to the desire geometry, and the joint, the filler and the triangular fillets are applied and mounted manuall.. The laminated are manufactured and cut into required dimensions which is show in the table

Bonded joints performed by gluing together pre-cured laminate with the suitable adhesives in this case the joint and the laminate is cured by epoxy itself [6]. Riveted joints made by using 3mm thick aluminum revert to hold joint as tight fit and proper Cashion should be taken minimize damage to the laminate during hole-drilling and closing of rivet [7]. Hybrid joints have a combination of adhesive bonding and mechanical fasteners. In the present case, rivet has been used as the mechanical fastener both steps are repeated to hybrids joints [8] all the dimension of three joint are made under same dimension of joint length, thickness, width, of 35mm, 2mm, 5mm and shown in figure 1 and investigation of joint were made room temperature.

Figure 1. Manufactured bonded, riveted and hybrid joints

IV. TESTING OF MANUFACTURED SPECIMENS

A universal tensile testing machine is used to perform variation of three joint in tensile strength was Predicted and it is validated experimentally. Consider the typical tensile specimen shown in figure 2. It has enlarged ends specimen held up between the grip sections. The most important concern in the a gripping method is to ensure the Minimum Bending and failure grip must be avoid. universal testing machine is fully automated with a variable-speed electric motor and a gear reduction system Which ensure the load was applied gradually and this motion loads the specimen in tension and compression. A feature of testing equipment is to control the speed of the machine accurately with microprocessor-based closed-loop servo system it is controlled through pc from load measurement to load control with the data acquisition system shown in the figure 3 Sample specimen size are tabulated in following table1.clamping force was given even to all three joint predict outcomes of result in standard manner.

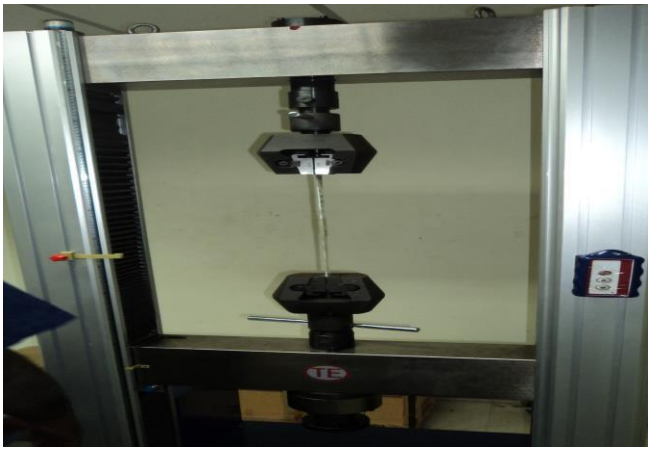

Figure 2. Specimens in universal testing machine

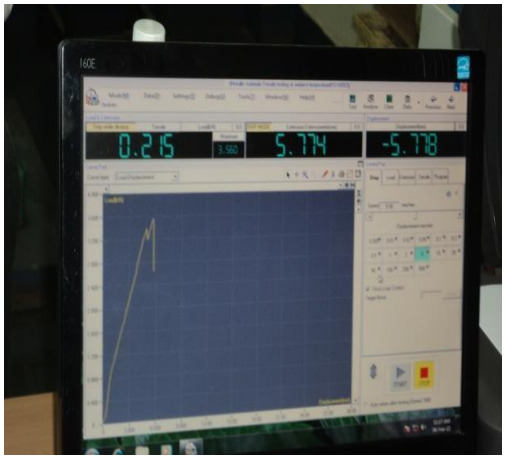

Figure 3. Data acquisition system output

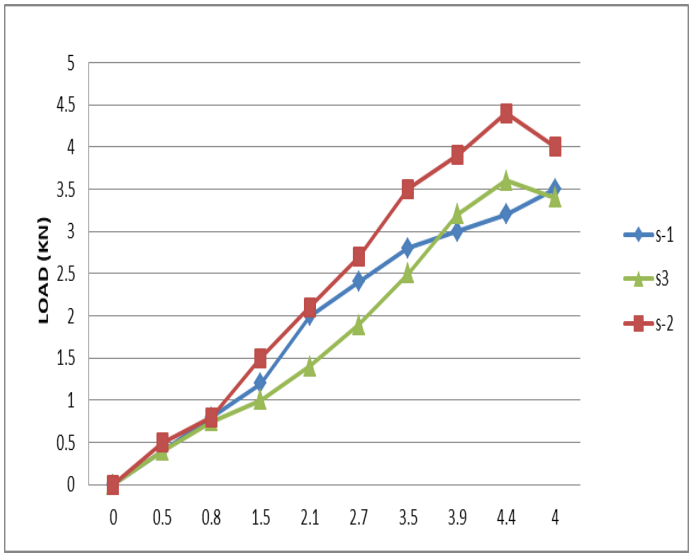
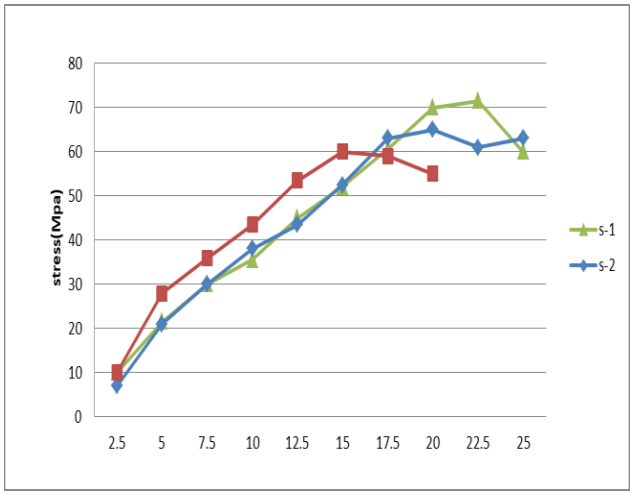
V. Results and Discussions

When we keen look the graph of all the three joint displacement to load pattern followed by hybrid joint was gradual and smooth cure when we compared to other two joint. this prevents the two major failure of composite joint such as crack arrest in the fibre and riveted joint has low strength when we compare other two joints the uneven strain rate of this is also void in the hybrid joint. while making the riveted joint strength of composite materials is reduced due to drilling of holes which incites crack propagation but incase hybrid joint crack growth rate is arrested by adhesive which is one reason for uniform stress strain pattern cure. another point of view in hybrid case rivet pin will proved bonding effect which minimize the peel stress of bonded joint which joint more effect efficient and high strength. the average breaking load hybrid joint is 1.25 times higher than bounded joint and 2.5 times higher than riveted joint which indicates the increase of tensile strength of joints. O.E. Can yurt*, investigated the effect of design on adhesive joints of thick composite sandwich structures. A simple but effective design can considerably improve the joint strength of thick adhesive composite joints. The joint under investigation consists of thick woven E-glass/vinyl ester laminates joined together with tongue and groove geometry. Longitudinal tensile loads were applied to the joints, resulting in large concentrated shear and peel stresses near the free edges of bond lines [4]. The following graphs shows the test results of bonded, riveted and hybrid joints.



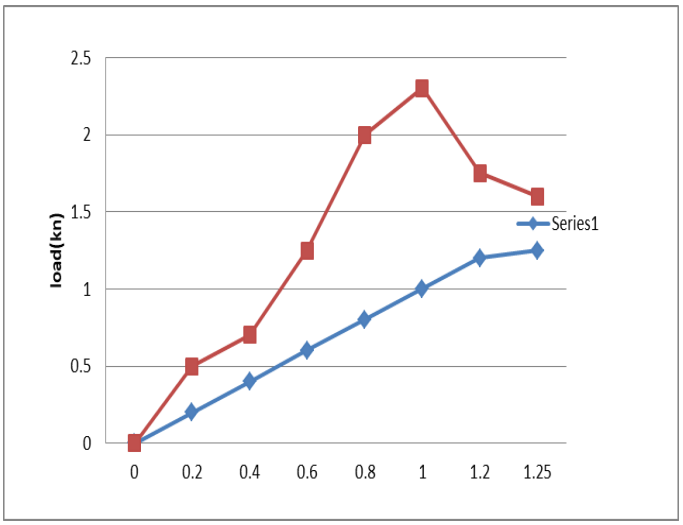
Bonded joints(kN) load vs Displacement (mm)



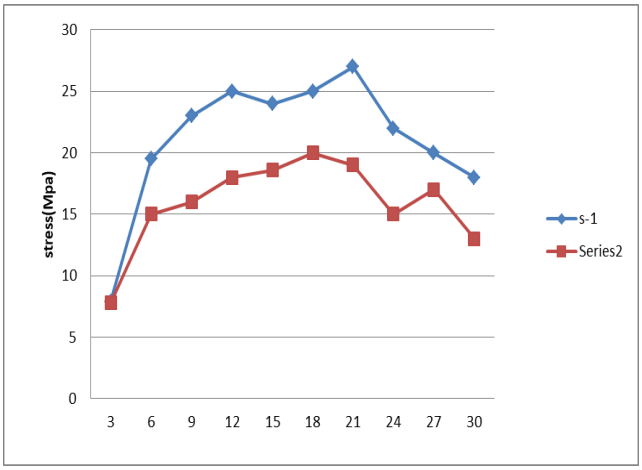
Bonded joints stress(MPa) vs strain(%)

5.1 Test results of bonded joints

5.2 Test results of Riveted joints

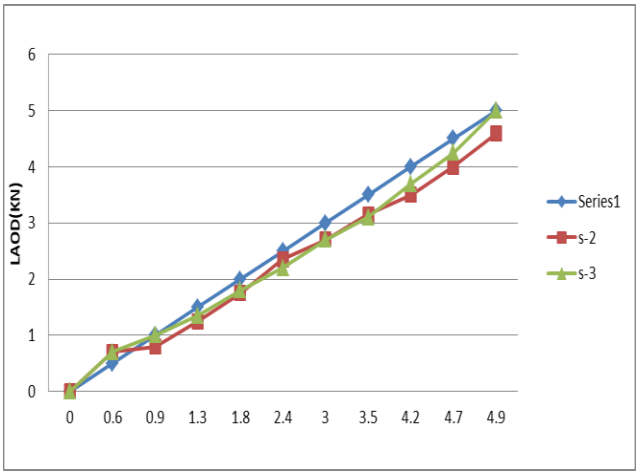


Riveted joints load(kN) vs Displacement (mm)

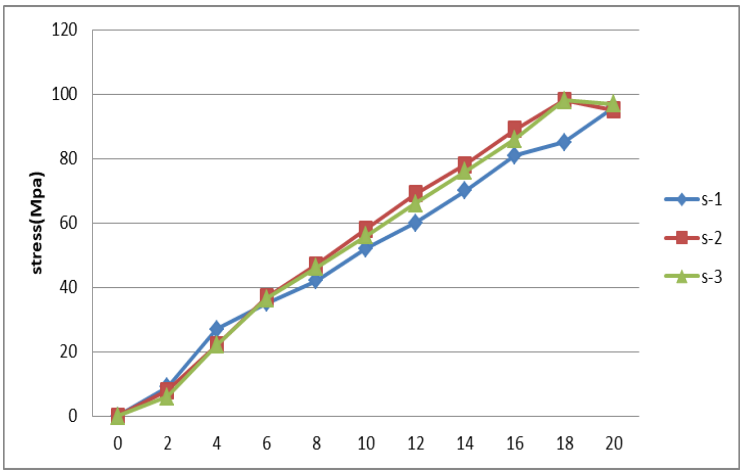


Riveted joints stress(MPa) vs strain (%)

5.3 Test results of Hybrid joints



Hybrid joints load(KN) vs Displacement(mm)



Hybrid joints stress (MPa) vs strain (%)

5.4 Result comparison of bonded, riveted and hybrid joints

Sample id	Ultimate tensile strength(Mpa)	Breaking load(kN)
Bonded Joint	66.6	4
Riveted Joint	23.2	2
Hybrid Joint	100.26	5

Since comparative study of strength of three joint is studied load was applied gradually until breaking load of joint is reached which is ultimate strength of joint. The outcomes of the experiment show that the hybrid joint with stands maximum breaking load of 5 kN and with ultimate strength of 100 Mpa.

Result and discussion

VI. CONCLUSION

This article focused on experimental study upon tensile strength of hybrid composite joints when compare with conventional joint. This indicate the hybrids joint will be satisfy the expatiation of current manufacturing industries and consumer. manufacture assure the quality with low cost. Thus from the present study, it was found that a well-designed hybrid joint is very efficient when compared to bonded or riveted joints in the case of repair situation in aircraft structures. We consider following criteria will design any composite joint such as thickness of adhesive joint must be based of loading condition and length of joint.

Abstract

This study investigates the performance and emission characteristics of a compression ignition engine fueled with palm oil biodiesel and hydrogen enrichment under varying load conditions. Experiments were conducted using neat diesel, palm oil biodiesel blends, and hydrogen-enriched palm biodiesel at different hydrogen flow rates. The results indicate that hydrogen supplementation significantly improves the combustion characteristics of biodiesel-fueled engine operation. The specific fuel consumption decreases and brake thermal efficiency increases with hydrogen enrichment due to the higher flame speed, better diffusivity, and wider flammability limits of hydrogen, which promote more efficient combustion. Emission analysis reveals that the addition of hydrogen to palm biodiesel substantially reduces carbon monoxide, unburned hydrocarbon, and smoke emissions as a result of improved oxidation and the carbon-free nature of hydrogen. However, nitrogen oxide emissions show an increasing trend with hydrogen enrichment, primarily due to the higher in-cylinder temperature and enhanced premixed combustion. Overall, the results demonstrate that hydrogen-enriched palm biodiesel can significantly enhance engine performance while reducing most harmful exhaust emissions, highlighting its potential as a promising alternative fuel for cleaner and more efficient diesel engine applications.

Key words: Palm biodiesel, Engine Pollution, alternate fuel, hydrogen

1. Introduction

The increasing demand for energy and growing environmental concerns have encouraged the exploration of renewable alternative fuels for compression ignition (CI) engines. Biodiesel has emerged as a promising substitute for petroleum diesel because it is biodegradable, renewable, and can be used in existing diesel engines with little or no modification. Biodiesel is typically produced through the transesterification of vegetable oils or animal fats to form fatty acid methyl esters (FAME) (Demirbas, 2009). Compared with conventional diesel fuel, biodiesel generally exhibits higher viscosity and lower calorific value, which may slightly increase fuel consumption, but its inherent oxygen content improves combustion efficiency and reduces harmful emissions (Knothe et al., 2010). Several studies have examined the performance and emission characteristics of biodiesel in diesel engines. Graboski and McCormick (1998) reported that biodiesel reduces carbon monoxide (CO), hydrocarbons (HC), and particulate matter emissions while slightly increasing nitrogen oxide (NOx) emissions. Agarwal (2007) demonstrated that biodiesel blends can be used in CI engines without major modifications and provide comparable performance to diesel fuel. Similarly, Lapuerta et al. (2008) observed improved combustion efficiency in biodiesel-fueled engines due to the oxygenated nature of the fuel. Hoekman et al. (2012) further confirmed that biodiesel reduces particulate emissions while maintaining acceptable engine performance. Among various biodiesel feedstocks, palm oil biodiesel has gained considerable attention due to its high oil yield and availability. Palm oil methyl ester exhibits favorable fuel properties such as good lubricity and combustion characteristics, making it suitable for diesel engine applications. Kalam and Masjuki (2002) investigated palm biodiesel in diesel engines and reported reduced smoke emissions compared with conventional diesel fuel. Hossain and Davies (2010) observed that palm biodiesel reduces CO and HC emissions due to improved oxidation during combustion. Mofijur et al. (2013) also reported lower smoke opacity and particulate emissions for palm biodiesel compared to diesel fuel.

In recent years, hydrogen has been investigated as a supplementary fuel to improve the combustion characteristics of diesel engines. Hydrogen possesses unique properties such as high flame speed, wide flammability limits, and high diffusivity, which promote rapid and efficient combustion. White et al. (2006) reported that hydrogen enrichment enhances engine efficiency and improves combustion stability. Saravanan and Nagarajan (2008) demonstrated that hydrogen induction in diesel engines significantly reduces CO and HC emissions. Verhelst and Wallner (2009) also reported that hydrogen enrichment improves thermal efficiency but may increase NOx emissions due to higher combustion temperatures. Several researchers have investigated hydrogen enrichment in biodiesel-fueled diesel engines. Saravanan et al. (2007) observed improved brake thermal efficiency and reduced smoke emissions when hydrogen was introduced into biodiesel-fueled engines. Banapurmath et al. (2010) reported that hydrogen supplementation enhances premixed combustion and reduces incomplete combustion products. Yilmaz et al. (2017) found that hydrogen–biodiesel dual-fuel operation improves combustion efficiency and reduces CO and HC emissions.

Overall, previous studies indicate that the combination of biodiesel and hydrogen enrichment can significantly improve engine performance and reduce emissions such as CO, HC, and smoke. However, hydrogen enrichment may lead to increased NOx emissions due to higher in-cylinder temperatures. Therefore, optimizing hydrogen flow rate and engine operating conditions is essential to achieve improved engine efficiency with controlled emissions.

2. Experimental setup

The setup consists of single cylinder, four stroke, CRDI VCR (Variable Compression Ratio) engine connected to eddy current dynamometer. It is provided with necessary instruments for combustion pressure, crank angle, airflow, fuel flow, temperatures and load measurements. These signals are interfaced to computer through high speed data acquisition device. The setup has stand-alone panel box consisting of air box, twin fuel tank, manometer, fuel measuring unit, transmitters for air and fuel flow measurements, process indicator and piezo powering unit. Rotameter are provided for engine cooling water flow measurement.

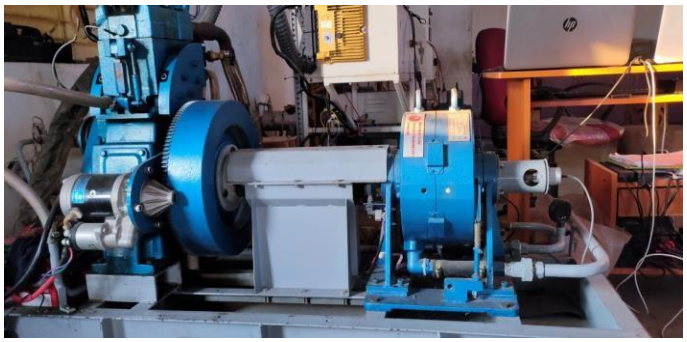

Figure 1: Engine Setup

Table 1 Specification of the Engine Setup

Engine Make	Kirloskar - Apex innovations Pvt. Ltd.
Type of Engine	CRDI VCR Engine
Number of Cylinders	Single cylinder, Four Stroke
Cooling Media	water cooled,
Rated Capacity	3.5 KW @ 1500 rpm,
Cylinder diameter	87.5 mm
Stroke length	110 mm,
Compression ratio range	12-18
Injection Pressure Variation	500, 550 and 600 bar
Data acquisition device	Make NI Instrument USA, NI USB-6210, 16-bit, 250kS/s.
Fuel tank Capacity 15 lit, Type:	Duel compartment, with fuel metering pipe of glass
Software	"Engine-soft" Engine performance analysis software
Loading type	Eddy current Dynamometer
Overall dimensions	W 2000 x D 2500 x H 1500 mm

3. Results and discussion

3.1. Specific fuel consumption

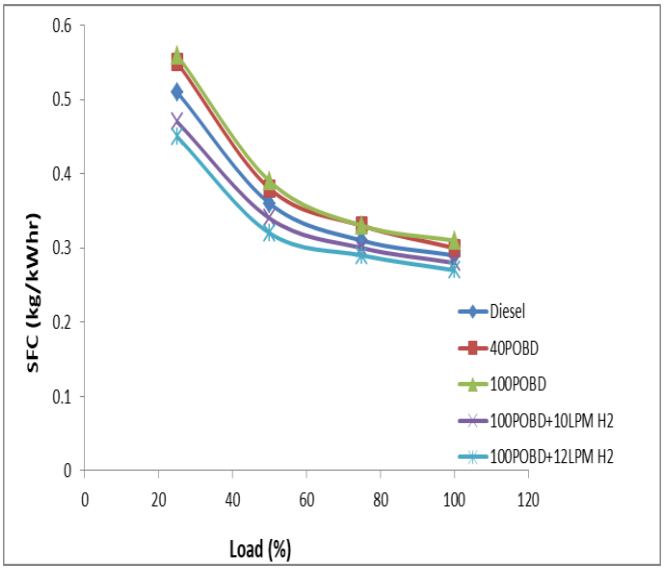

Figure 2: Specific fuel consumption variation with load

The variation of specific fuel consumption (SFC) with load shows that SFC decreases for all tested fuels as engine load increases. At 25% load, neat diesel shows an SFC of about 0.51 kg/kWh**,** while 40POBD and 100POBD exhibit higher values of approximately 0.55 kg/kWh and 0.56 kg/kWh, respectively, due to the lower calorific value of biodiesel. When hydrogen is inducted with palm biodiesel, the SFC decreases to about 0.47 kg/kWh for 100POBD **+** 10 LPM H_2 and 0.45 kg/kWh for 100POBD + 12 LPM H_2. A similar trend is observed at full load, where SFC reduces to around 0.29 kg/kWh for diesel**,** 0.30 kg/kWh for 40POBD**,** 0.31 kg/kWh for 100POBD**,** 0.28 kg/kWh for 100POBD + 10 LPM H_2**,** and 0.27 kg/kWh for 100POBD + 12 LPM H_2**.** The reduction in SFC with hydrogen enrichment is attributed to the higher flame speed and improved combustion characteristics of hydrogen, which enhance combustion efficiency and reduce fuel consumption.

3.2. Brake Thermal Efficiency

The brake thermal efficiency (BTE) increases with increasing engine load for all tested fuels due to improved combustion and better utilization of the supplied fuel energy. At 25% load, the BTE of neat diesel is about 19%, while 40POBD and 100POBD show slightly lower efficiencies of around 16.5% and 17%, respectively, mainly because of the lower calorific value and higher viscosity of biodiesel. With hydrogen enrichment, the BTE improves to approximately 18.5% for 100POBD + 10 LPM H_2 and 20% for 100POBD + 12 LPM H_2.

At full load (100%), diesel achieves a BTE of about 32%, whereas 40POBD and 100POBD reach around 30.5% and 30%, respectively. The addition of hydrogen further enhances efficiency, giving 32.5% for 100POBD + 10 LPM H_2 and the highest value of about 33.5–34% for 100POBD + 12 LPM H_2. The improvement in BTE with hydrogen addition is attributed to its high flame speed, wide flammability limits, and rapid diffusion, which promote faster and more complete combustion. As a result, hydrogen-enriched palm biodiesel—especially with 12 LPM hydrogen—shows the highest brake thermal efficiency among the tested fuels.

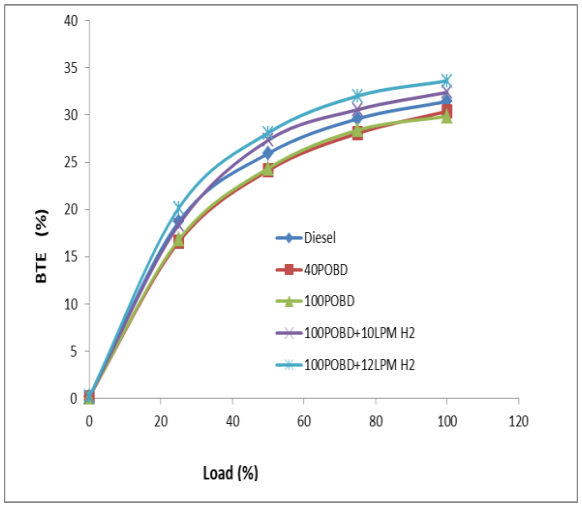

Figure 3: Brake thermal efficiency variation with load

3.3. Carbon monoxide

The variation of carbon monoxide (CO) emissions with engine load for different fuels indicates that CO emissions generally increase with increasing load due to richer fuel–air mixtures and incomplete oxidation at higher fuel injection rates. At no load, neat diesel produces the highest CO emission of about 0.06% vol, while 40POBD and 100POBD show lower values of approximately 0.035% and 0.025%, respectively. The addition of hydrogen significantly reduces CO emissions, with 100POBD + 10 LPM H_2 producing about 0.02% and 100POBD + 12 LPM H_2 about 0.01%, owing to improved combustion and enhanced oxidation of CO to CO_2. As the load increases to 100%, CO emissions rise for all fuels. Diesel shows the highest value of around 0.24%, followed by 40POBD (≈0.21%) and 100POBD (≈0.20%). In contrast, hydrogen-enriched biodiesel results in much lower CO emissions, with 100POBD + 10 LPM H_2 producing about 0.125% and 100POBD + 12 LPM H_2 about 0.115%. The reduction in CO emissions with hydrogen enrichment is attributed to hydrogen's high flame speed, wider flammability range, and absence of carbon, which promote more complete combustion and improved oxidation of carbon monoxide.

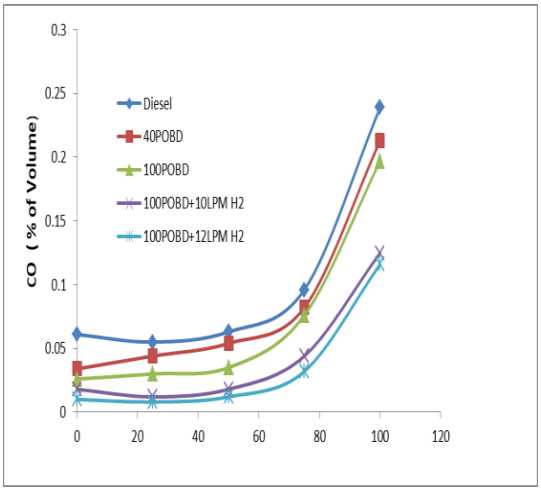

Figure 4: Carbon monoxide emission variation with load

3.4. Unburned hydrocarbon

The variation of unburned hydrocarbon (UBHC) emissions with engine load shows that UBHC increases with increasing load for all tested fuels due to richer fuel–air mixtures and incomplete combustion at higher fuel supply rates. At no load, neat diesel produces the highest UBHC emission of about 50 ppm, whereas 40POBD and 100POBD show lower values of approximately 37 ppm and 30 ppm, respectively. Hydrogen enrichment further reduces UBHC emissions, with 100POBD + 10 LPM H_2 producing around 27 ppm and 100POBD + 12 LPM H_2 about 22 ppm indicating improved combustion characteristics. At full load (100%), UBHC emissions increase significantly for all fuels. Diesel shows the highest emission of about 116 ppm, followed by 40POBD (≈90 ppm) and 100POBD (≈82 ppm). The addition of hydrogen results in comparatively lower UBHC emissions, with 100POBD + 10 LPM H_2 producing about 78 ppm and 100POBD + 12 LPM H_2 about 70 ppm. The reduction in UBHC emissions with hydrogen enrichment is attributed to hydrogen's high flame speed, better diffusivity, and wider flammability limits, which enhance combustion efficiency and promote more complete oxidation of the fuel-air mixture.

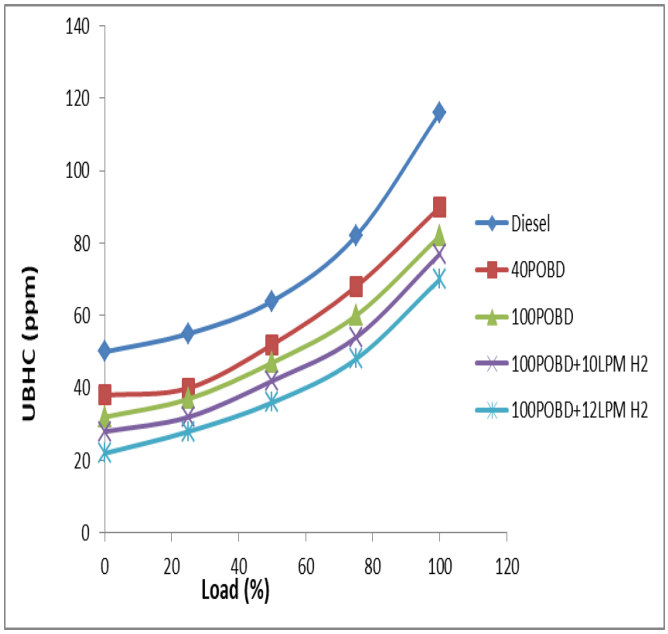

Figure 5 Unburned hydrocarbon emission variation with load

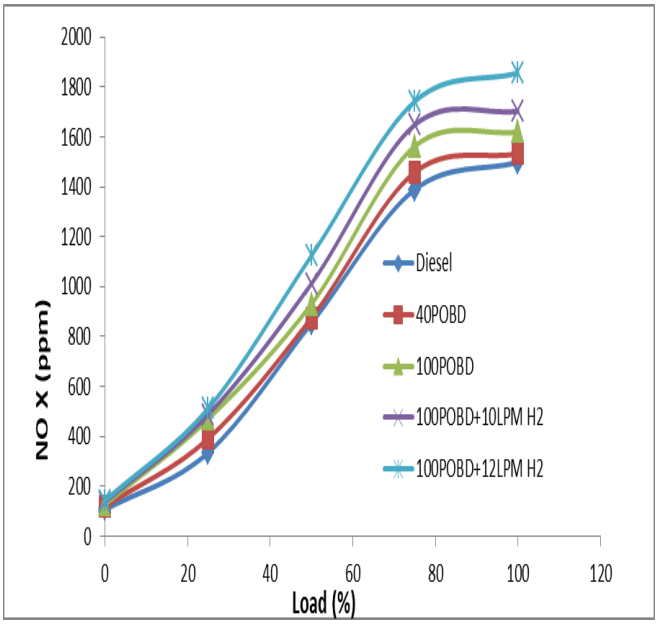

Figure 6: Nitrogen oxide emission variation with load

3.5. Nitrogen oxide

The variation of nitrogen oxide (NOx) emissions with engine load shows that NOx increases significantly with increasing load for all tested fuels due to higher combustion temperature and increased oxygen availability during combustion. At no load, NOx emissions are relatively low, with diesel producing about 120 ppm, while 40POBD and 100POBD show similar values of around 110–115 ppm. Hydrogen enrichment slightly increases NOx, with 100POBD + 10 LPM H_2 producing about 125 ppm and 100POBD + 12 LPM H_2 about 130 ppm. As the load increases to 100%, NOx emissions rise considerably. Diesel produces about 1500 ppm, while 40POBD and 100POBD show slightly higher values of approximately 1550 ppm and 1620 ppm, respectively. With hydrogen addition, NOx emissions further increase to around 1700 ppm for 100POBD + 10 LPM H_2 and reach the highest value of about 1850 ppm for 100POBD + 12 LPM H_2. The increase in NOx emissions with hydrogen enrichment is mainly attributed to higher in-cylinder temperature, faster combustion, and improved premixed combustion caused by hydrogen's high flame speed and wider flammability limits, which promote thermal NOx formation at elevated loads.

3.6. Smoke

The variation of smoke opacity with engine load indicates that smoke emissions increase with increasing load for all tested fuels due to the higher fuel injection rate and incomplete combustion at rich mixture conditions. At no load, diesel produces the highest smoke opacity of about 16%, while 40POBD and 100POBD show lower values of around 14% and 8%, respectively. Hydrogen enrichment further reduces smoke emissions, with 100POBD + 10 LPM H_2 producing about 8% and 100POBD + 12 LPM H_2 about 7%, due to improved combustion characteristics. As the load increases to 100%, smoke opacity rises significantly for all fuels. Diesel records the highest value of around 72%, followed by 40POBD (≈68%) and 100POBD (≈66%). In contrast, hydrogen-enriched biodiesel shows comparatively lower smoke emissions, with 100POBD + 10 LPM H_2 producing about 64% and 100POBD + 12 LPM H_2 about 63%. The reduction in smoke emissions with hydrogen enrichment is mainly attributed to hydrogen's carbon-free nature, high flame speed, and improved air–fuel mixing, which promote more complete combustion and reduce soot formation.

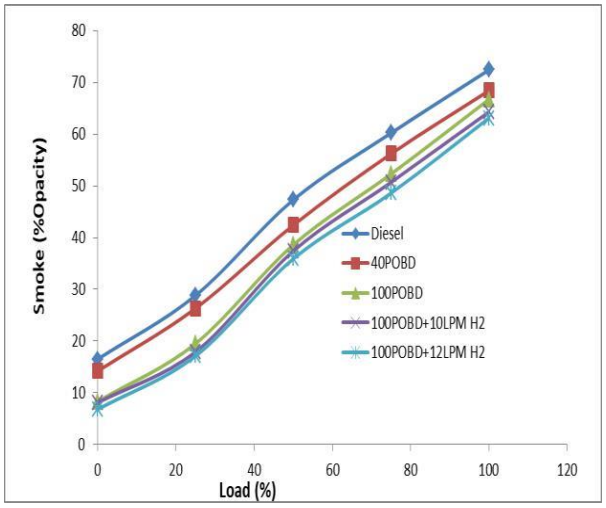

Figure 7: Smoke opacity emission variation with load

Conclusion

The experimental results demonstrate that the addition of hydrogen significantly improves the performance and emission characteristics of a palm biodiesel-fueled diesel engine.

- The specific fuel consumption (SFC) decreased with hydrogen enrichment, where 100POBD + 12 LPM H_2 showed the lowest SFC of about 0.27 kg/kWh at full load, compared to 0.29 kg/kWh for diesel and 0.31 kg/kWh for neat palm biodiesel, indicating improved fuel utilization. Correspondingly, the brake thermal efficiency (BTE) increased with hydrogen addition, reaching a maximum of about 33–34% for 100POBD + 12 LPM H_2, which is higher than diesel (≈32%) and neat biodiesel (≈30%), due to hydrogen's high flame speed and better combustion characteristics.
- In terms of emissions, CO and HC emissions were significantly reduced with hydrogen enrichment. At full load, CO emissions decreased from about 0.24% for diesel to around 0.115% for 100POBD + 12 LPM H_2, while HC emissions decreased from about 116 ppm for diesel to around 70 ppm with hydrogen supplementation. Similarly, smoke opacity was also reduced, with 100POBD + 12 LPM H_2 showing about 63% smoke at full load compared to 72% for diesel, due to the carbon-free nature of hydrogen and improved oxidation of soot precursors. However, NOx emissions increased with hydrogen addition, reaching about 1850 ppm for 100POBD + 12 LPM H_2, compared to 1500 ppm for diesel, mainly due to higher in-cylinder temperatures and enhanced combustion.

Overall, the results indicate that hydrogen enrichment, particularly at 12 LPM, effectively enhances engine efficiency and reduces CO, HC, and smoke emissions while slightly increasing NOx emissions, making hydrogen-enriched palm biodiesel a promising alternative fuel for cleaner and more efficient diesel engine operation.

ABSTRACT

Austempered Ductile Iron (ADI) is utilized extensively in engineering applications because of its exceptional mechanical qualities, which include toughness, high strength, and resistance to wear. However, ADI's high hardness and abrasive character make machining it difficult and can result in poor surface finish and rapid tool wear. The machining behavior of ADI is examined in this work utilizing wire electric discharge machining (WEDM) and surface grinding techniques. Analysis was done on the effects of grinding and WEDM process parameters on surface properties and variations in hardness. ADI Grade 1 specimens were machined and tested with one pass (AD1), three passes (AD2), and five passes (AD3) of WEDM. Mechanical characteristics such surface roughness, microhardness, and Brinell hardness were assessed using established testing protocols. The findings of the experiment showed that the number of machining passes has a major impact on the hardness and surface integrity of ADI specimens. The specimen with five passes (AD3) had the lowest surface roughness and the highest microhardness and Brinell hardness values among the examined samples. The primary causes of this improvement are the removal of recast layers throughout several passes and the conversion of residual austenite into martensite. The findings show that increasing the number of WEDM passes improves the ADI components' machining quality, making them appropriate for demanding applications like railway coupler heads.

Keywords: Austempered Ductile Iron; WEDM; Microhardness; Brinell hardness; surface roughness.

I INTRODUCTION

The exceptional combination of strength, toughness, wear resistance, and fatigue performance of austempered ductile iron (ADI) has drawn a lot of interest in contemporary engineering applications. Acicular ferrite and high-carbon stabilized austenite make up the distinctive microstructure of ADI, which is created by subjecting ductile iron to a regulated heat treatment procedure called austempering[1]. This microstructure maintains reduced manufacturing costs while offering better mechanical qualities than many alloy steels and ordinary ductile irons. These benefits have led to the widespread usage of ADI in agricultural machinery, gears, crankshafts, automotive components, and structural applications[2].

The exceptional combination of strength, toughness, wear resistance, and fatigue performance of austempered ductile iron (ADI) has drawn a lot of interest in contemporary engineering applications[3]. Acicular ferrite and high-carbon stabilized austenite make up the distinctive microstructure of ADI, which is created by subjecting ductile iron to a regulated heat treatment procedure called austempering. This microstructure maintains reduced manufacturing costs while offering better mechanical qualities than many alloy steels and ordinary ductile irons. These benefits have led to the widespread usage of ADI in agricultural machinery, gears, crankshafts, automotive components, and structural applications[4].

In the manufacturing sector, surface grinding is a common machining technique used to create flat surfaces with excellent surface quality and high accuracy. A revolving abrasive wheel is used in the procedure to microcut particles off the surface of the workpiece. The machined component's overall quality and surface roughness are greatly influenced by factors like feed rate, depth of cut, and grinding speed[5]. Therefore, maximizing the grinding performance requires an understanding of these parameters' effects.

For the machining of hard and challenging-to-machine materials, non-traditional machining methods like Wire Electric Discharge Machining (WEDM) have grown in significance alongside conventional machining procedures[6-8]. A sequence of regulated electrical discharges between a thin wire electrode and the work piece in the presence of a dielectric fluid cause material removal in WEDM, a thermal erosion process. Because there is no direct mechanical contact between the tool and the workpiece, the method is especially well suited for materials with high strength and hardness[9].

Current, pulse on time, pulse off time, wire tension, voltage, and feed rate are some of the process variables that affect WEDM machining performance[10]. The rate of material removal, surface roughness, dimensional accuracy, and the recast layer generation on the machined surface are all directly impacted by these characteristics. Furthermore, WEDM frequently uses numerous cutting passes to enhance surface smoothness and minimize surface flaws[11,12].

Fig. 1 Austempered Ductile iron Coupler Head

The present study focuses on the machining of ADI using surface grinding and Wire Electric Discharge Machining processes. The influence of various machining parameters on surface characteristics and hardness variation is investigated. Furthermore, the effect of different numbers of passes in the WEDM process on the surface quality of ADI specimens is analyzed. The results obtained from this study provide valuable insights for improving machining performance and achieving better surface integrity in ADI components.

II. MATERIALS AND METHODS

2.1 Materials

Figure 1 shows the coupler head which has been made of Austempered ductile iron (ADI). ADI with Grade 1 is used in this research work (Fig.2 & Fig.3). Various grades of Austempered ductile irons are produced by heat-treating cast ductile iron by adding small amount of elements such as nickel, molybdenum, or copper to get reliable hardenability. Table 1 shows the chemical composition for the given material. The physical properties of ADI are presented in Table 2.

2.2 Experimental Methods

2.2.1 Surface Grinding

Surface grinding is done on the work piece before machining with a surface grinder. The grinding wheel consists of abrasive particle and silicon carbide etc. The speed of the grinding wheel is 800 RPM 2500 RPM. The feed rate time was calculated by using a stopwatch. Depth of cut is one of the major influence factors of surface roughness. Fig. 4. shows the surface grinding machine. This grinding machine only applicable to the ferromagnetic materials. Because of the magnetic chuck used as the work holding device. Normally the grinding

wheel consists of abrasive slurry and synthetic materials. Table 3 shows the different level of input parameters speed, Depth of Cut and feed time. Machined work piece surface roughness value measured by a conventional stylus probe.

Sl.No	Parameters Range	Unit	Range
1	Speed	rpm	1100 – 1500
2	Time	min	1.5 – 6
3	Depth of Cut	mm	0.1 – 0.9

2.2.2 Wire Electric Discharge Machining (WEDM)

A schematic illustration of the cutting machine is shown in Fig. 5. The electrode was made of a 0.25 mm diameter copper wire. The dielectric fluid used was deionized water with a flow rate of 35/min. Parameters for controlling the working conditions are listed in Table 4; including the available setting range and the actual setting range used in this study. The on-time was set in the range of 0-16 µs and the off-time was 0-16 µs. The copper wire tension was set in the range of 0-12N. The cutting feed rate (m/min) of EDWC was set up as feedrate override 0-12 of the working table (controlled by the machine in this study), (mm/min) multiplied by thickness of workpiece (mm); that is, the area cut by the copper wire per unit time. The dimensions of cut specimens were measured by a micrometer. The variation of hardness in the remelted layer was measured by the Vicker's hardness test in which a hardness was determined from the average of six tests measuring one area of specimen. The remelted layer judged from the variation of hardness was compared with the results from the optical observation. Surface roughness Ra of cut specimens was measured by a surface roughness meter.

III. EXPERIMENTAL

3.1 Mechanical Behavior

Three samples AD1, AD2 and AD3 were tested in this study. The Rockwell Hardness and Brinell Harness Testing Machines were used to evaluate hardness behaviour in accordance with ASTM E18 and ASTM E10, respectively. The samples of machined austempered ductile iron is subjected to hardness behaviour are shown in Figure 7.

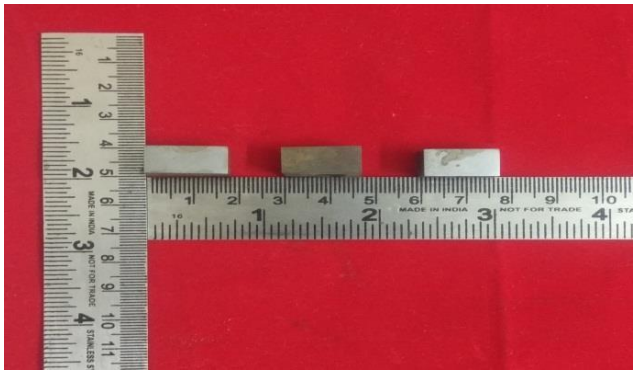

Fig. 7 Hardness Test Samples of AD1, AD2, AD3

Rockwell Hardness Number (RHN) = $N - \frac{h}{s}$ (1)

Where N denotes the number of specific Rockwell hardness units, h denotes the permanent depth of an indentation in millimeters, and s denotes the scale unit.

Steel ball indenter scale of 130 units,

Brinell Hardness Number (BHN) = 0.102 x

$$\frac{2F}{\pi D(D-\sqrt{D^2-d^2}}$$ (2)

Where F is the test force in N, D is the ball diameter in mm, and d is the indentation's mean diameter in mm.

3.1.1 Micro Hardness

The test is performed according to the ASTM E92 standard with a diamond indenter of 1kg applied load to the material surface for a dwell time of 6 seconds. Hardness measurement is done to find the micro hardness of the machined AD1, AD2 and AD3 specimens. This was performed on a cross section of coatings with a load of 1.96N and a dwell period of 14 sec.

3.1.2 Surface Roughness

The real surface's deviations from its ideal surface in the normal vector direction are measured using surface roughness. Furthermore, it is a good predictor of mechanical behavior and adhesion. Additionally, it is measured using the fashionable prose that is affixed to the surface profilometer in accordance with ASTM D7127. A diamond stylus is moved laterally across the sample for a predetermined distance and contact force after making vertical contact with the surface. It gauges minute surface changes in the location and displacement of the vertical stylus as a function. The roughness range that a common profilometer can measure is 12 nm to 1 mm. The height position of the stylus generates an analog signal and then into a digital signal which can be stored, analyzed and displayed. The radius of diamond stylus ranges between 30 nm to 60µm and their horizontal resolution can be controlled using the scan speed and data signal sampling rate. The stylus tracking force can range from less than 1 to 40 mg.

IV. RESULTS AND DISCUSSION

4.1 Mechanical Behavior

4.1.1 Micro hardness

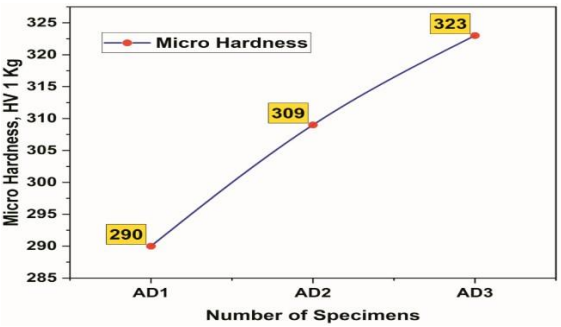

Fig. 8 Micro Hardness of the Machined Specimens

The sized and machined specimens of Austempered ductile Iron subjected to test loads are shown in Fig. 8. Specimen AD3 has more hardness values than Specimens AD1 and AD2 as shown in Fig.8. The austenite is mechanically and thermally stable due to carbon diffusion during heat treatment, but it can transform into martensite during the plastic deformation phase. With respect to chip formation, this effect can lead to a very high mechanical specific load on the cutting edge. The strain hardening effects described in crush and flow curves can also be detected by micro hardness measurements. Compared to AD1 and AD2, AD3 shows the strongest increase in micro hardness by quasi-static deformation. One explanation is provided by measuring the residual austenite: In ductile ADI grades more austenite can be detected in the microstructure due to increased graphite content as a result of higher tempering temperatures. This austenite transforms almost completely into martensite during deformation independently of the strain rate. As a result, the micro hardness increases due to a higher level of martensite. The Variations in hardness is mainly because of the microstructures created in the specimens due to number of passes in machining. This AD3 specimen with a high micro hardness (HV) can be used for the manufacture of railways coupler head.

4.1.2 Surface Roughness

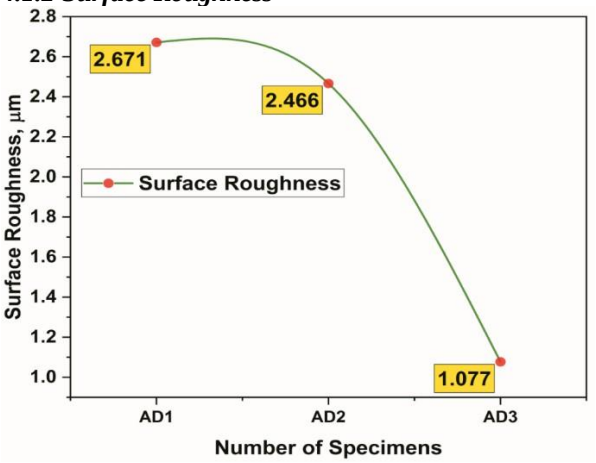

Fig. 9 Surface Roughness of the Machined Specimen

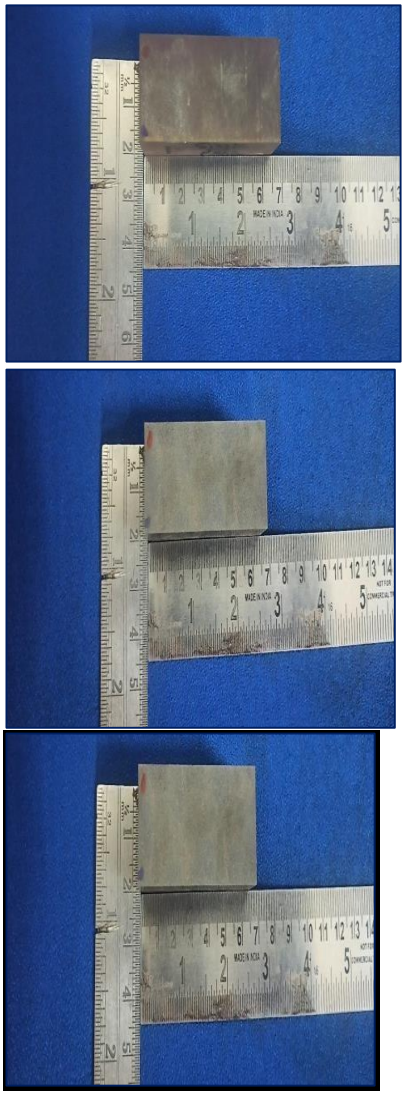

Fig. 10 Surface Roughness of Austempered Ductile Iron Specimens (AD1, AD2, AD3)

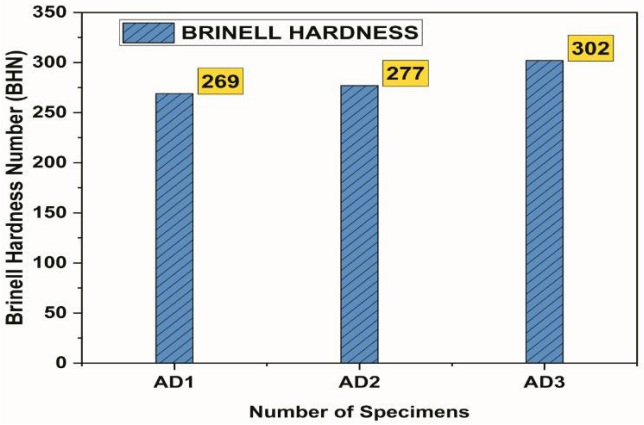
The sized and machined specimens of Austempered ductile iron are shown in Figure 10. According to Fig10. Specimen AD3 has a lower surface roughness compared to AD1 and AD2. Spark gap voltage and tension of wire are major factors in getting good surface finish. Less spark gap voltage and high wire tension will reduce the chance of getting a coarse structure by reducing the electric field and vibrational ignorance. This AD3 specimen with less roughness can be used for the manufacturing of coupler heads in railways.

4.1.3 Brinell Hardness

Fig. 11 Brinell Hardness of ADI Specimens

The fabricated and sized specimen of the ADI subjected to the Brinell load of 2400 kgf is shown in Figure 11. Specimen AD3 has a higher Brinell hardness value than Specimens AD1 and AD2.The addition of passes causes deposition of melted ADI resulted in a higher Brinell hardness value in Specimen AD3. The incorporation of various oxide deposit withstands the load applied and enriches the hardness of the ADI sample. This AD3 specimen with a high Brinell hardness value can be used to build the coupler head.

V. CONCLUSIONS



The present study investigated the machining behavior of Austempered Ductile Iron (ADI) using surface grinding and Wire Electric Discharge Machining (WEDM) processes. The influence of machining parameters and the number of passes on mechanical properties such as microhardness, Brinell hardness, and surface roughness was analyzed. Based on the experimental results, the following conclusions are drawn:

1. The machining performance of ADI is significantly influenced by the number of passes during the WEDM process. Increasing the number of passes improves the surface quality and mechanical characteristics of the machined specimens.

2. Among the tested specimens, AD3 (five passes) exhibited the highest microhardness value compared to AD1 (one pass) and AD2 (three passes). This improvement is mainly due to the transformation of retained austenite into martensite during machining and the strain hardening effect.

3. Surface roughness results showed that AD3 produced the lowest surface roughness, indicating that multiple machining passes help remove irregularities and recast layers formed during the initial machining stage.

4. The Brinell hardness value of AD3 was higher than that of AD1 and AD2, which can be attributed to the deposition of melted material and formation of oxide layers during repeated WEDM passes.

5. The combined improvement in hardness and surface finish indicates that increasing the number of machining passes enhances the overall surface integrity of ADI components.

6. Based on the obtained results, the AD3 specimen with five machining passes demonstrates superior mechanical properties and surface quality, making it suitable for applications such as railway coupler head manufacturing, where high strength, wear resistance, and durability are required.

ABSTRACT

A study conducted on tungsten inert gas welded AISI 409 Ferrite stainless steel which has application of heat exchanger. In this study process parameters welding current, arc voltage, bevel angle and work piece gap are considered. The L9 Orthogonal array is utilized for experimental plan. The Reponses yield strength, ultimate tensile strength, hardness and percentage elongation are measured as per the ASTM standard. The microstructure characteristics observed using optical microscope at base metal, heat affected zone and weld zone. The TAGUCHI Analysis conducted to find out optimum level of parameters. ANOVA of regression model helps to find out significant factors to get maximum ultimate tensile strength and hardness. High intensity of welding current helps to attain high tensile strength and high value of bevel angle, workpiece gap are leads to lower the tensile strength. Microstructure of heat shows that martensitic formation in weld bead. affected zone

Keywords: Tensile Strength, Hardness, Microstructure, Orthogonal Array, Taguchi Analysis

Introduction

Ferritic stainless steels are body centered cubic crystal structure. Chromium present in the range of 10.5–11.75%. When compared to the austenitic grades, they are rather weak at higher temperatures, although having good ductility and formability. Chemical processing equipment, furnace parts, heat exchangers, oil burner components, storage vessels, electrical appliances, solar water heaters, and household appliances are all made using it in less harshly corrosive environments [1]. Because it creates high-quality welds, the TIG welding technique is one of the most widely used methods for welding thin materialsin manufacturing industries. However, when thick materials are fused in a single pass, TIG welding has poorer joint penetration than metal inert gas welding. For stainless steel butt joints, single pass TIG welding using argon as shielding gas is typically restricted to a depth of 3 mm. As a result, increasing TIG welding's penetration capacity and manufacturing productivity is essential [2-5]. Among the most well-known methods is the combination of TIG welding and activating flux. In order to create an activating flux, powdered materials including oxides, chlorides, and fluorides are usually mixed with acetone or ethanol to create a substance that resembles paint. Prior to welding, the surface of the joint to be welded was lightly coated with flux [6-10]. The non-consumable tungsten electrode used in gas tungsten arc welding is protected against impurities by the inert gas when new gases like argon or helium are used. Among the several welding methods,The GTAW welding process yields a precise and superior weld [11-13]. Researchers have recently attempted to use flux, additional elements, electromagnetic stirring, and ultrasonic aid to address these issues [14]. Investigated how Cu and Al components affected the welded junction when 430 FSS was being welded [15]. The outcome shown that the method greatly improved grain refinement, which improved the welded joints' strength, toughness, and resistance to pitting [16]. In this current study optimization of process parameters using Taguchi analysis to predict tensile strength and hardness carried out along with microstructure study of TIG welded AISI 409 Ferritic Stainless Steel.

Materials & Methods

AISI 409 is an inexpensive ferritic stainless steel (10.5–11.75% chromium) intended for corrosion-resistant, high-temperature applications where aesthetics are not important, mainly automotive exhaust systems. Mostly Fe-11Cr, with titanium stabilization for welding and little nickel (<0.5%). It is appropriate for automobile exhaust gasses since it is lower than 430 but superior to martensitic grades like 410. Excellent resistance to oxidation, appropriate for continuous use up to 675°C and operates sporadically up to 815°C. Its ferritic structure guarantees its magnetic properties. The specimen prepared for welding is shown in figure 1and welded specimen shown in figure 2. Specimens subjected to tensile test and hardness test shown in figure 3 and 4 respectively.

The Rank in S/N ratio shows that current plays a most role for attaining the high yield strength and other factors are less significant.

1. Taguchi Analysis:

Taguchi analysis is a robust optimization technique used to improve the quality and efficiency of manufacturing processes by minimizing variations and optimizing process parameters. It is based on the design of experiments (DOE) methodology and uses orthogonal arrays to systematically test different combinations of input parameters with a minimal number of experiments.Orthogonal Arraysare predefined experimental setups that help in systematically varying multiple parameters while reducing the number of required experiments.Signal-to-Noise (S/N) Ratio is the main performance metric in Taguchi analysis. It measures the quality characteristics based on three possible objectives. Smaller-the-better (e.g., minimizing defects or errors), Larger-the-better (e.g., maximizing strength or efficiency) and Nominal-the-best (e.g., achieving a target value). In this work responses measured are ultimate tensile strength and hardness. The response requires high value, therefore larger the best category is selected. The equation no.1 is used to calculate S/N ratio but Minitab Software is used for Taguchi Analysis.

Larger the best characteristics:

$$S/N\ Ratio(\eta) = -10\log_{10}\left(\frac{1}{r}\sum_{i=1}^{r}\frac{1}{y_{ij}^2}\right) \quad (1)$$

1.1 Yield strength

Yield strength is a crucial mechanical property of a welded joint that defines the stress level at which the material begins to deform plastically. In **TIG welding**, the yield strength of the weldment is influenced by various factors, including welding parameters, heat input, cooling rate, and metallurgical transformations.The TIG samples are prepared based on the L9 Orthogonal array. The Taguchi analysis is used to predict optimum level to get maximum yield strength of the joint. The linear regression model is also prepared to predict the results in advance.

1.1.1 TAGUCHI Analysis for Yield Strength

The S/N ratio calculated for yield strength related to larger the best category as per equation 1. The S/N ratio for yield strength and ranking of parameters tabulated in table 4.The S/N ratio plot for yield strength is shown in

Table 4.The S/N Ratio Analysis of Yield Strength.

Rank	1	2	4	3

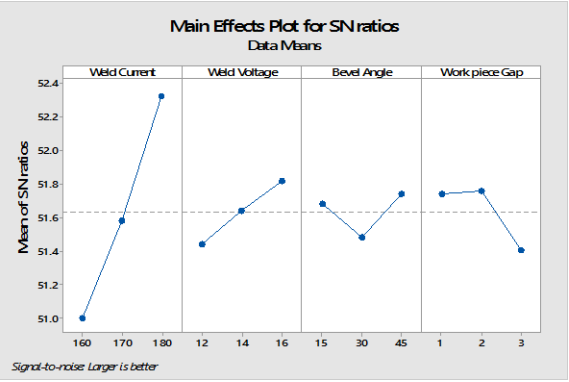

Figure 5.SN Ratio Plot for Yield Strength

1.2 Ultimate Tensile Strength

Ultimate tensile strength (UTS) is a critical mechanical property that defines the maximum stress a welded joint can withstand before failure. It represents the material's resistance to tensile loading and is an essential factor in determining the structural integrity of welded components. In **TIG welding**, the UTS of the weldment are influenced by welding parameters, heat input, cooling rate, and metallurgical changes in different zones of the joint. The TIG welded samples are prepared based on the L9 Orthogonal array. The Taguchi analysis is used to predict optimum level to get maximum tensile strength of the joint. The linear regression model is also prepared to predict the results in advance.

1.2.1 TAGUCHI Analysis for Ultimate Tensile Strength

The S/N ratio calculated for Ultimate Tensile Strength related to larger the best category as per equation 1. The S/N ratio for yield strength and ranking of parameters tabulated in table 5.The S/N ratio plot for tensile strength is shown in fig.6.The optimal level of factor identified as $A_3B_3C_2D_1$.The high value of current, voltage, medium value of bevel angle and low value of work piece gap are optimized level of factors to get maximum Ultimate Tensile strength. The Rank in the SN ratio shows that the process parameters current and voltage plays a vital role for attaining the high maximum Ultimate Tensile strengthand other factors are less significant.

1.3 Percentage Elongation

Percentage elongation is a key mechanical property that indicates the ductility of a welded joint. It measures the material's ability to undergo plastic deformation before fracture under tensile loading. Higher elongation values suggest good ductility, while lower values indicate brittleness, which may lead to premature failure.The TIG welded samples are prepared based on the L9 Orthogonal array. The Taguchi analysis is used to predict optimum level to get maximum Percentage Elongation of the joint. The linear regression model is also prepared to predict the results in advance.

1.3.1 TAGUCHI Analysis for Percentage Elongation

The S/N ratio calculated for Percentage Elongation related to larger the best category as per equation 1. The S/N ratio for Percentage Elongation and ranking of parameters tabulated in table 6.The S/N ratio plot for tensile strength is shown in fig.7.The optimal level of factor identified as $A_3B_3C_2D_1$.The high value of current, voltage, medium value of bevel angle and low value of work piece gap are optimized level of factors to get maximum Percentage Elongation. The Rank in the SN ratio shows that the process parameters current and Work piece Gap plays a

vital role for attaining the high Percentage Elongationand other factors are less significant.

1.4 Hardness at base metal

The hardness of a welded joint is a critical mechanical property that determines its ability to resist deformation, wear, and fatigue. It is influenced by several factors, including welding parameters, heat input, cooling rate, and material composition. In TIG welding, hardness variations in the welded joint occur due to microstructural changes in different zones like weld zone Hardness depends on solidification characteristics and possible alloying effects. Heat-Affected Zone often shows hardness variations due to grain growth, phase transformations, and possible softening or hardening effects. Base Metal typically retains its original hardness unless affected by heat input.

1.4.1 TAGUCHI Analysis for Hardness at base metal

The S/N ratio calculated for Hardness at base metal related to larger the best category as per equation 1. The S/N ratio for Hardness at base metal and ranking of parameters tabulated in table 7.The S/N ratio plot for Hardness at base metal is shown in fig.8.The optimal level of factor identified as $A_2B_2C_1D_1$.The high value of current, voltage, medium value of bevel angle and low value of work piece gap are optimized level of factors to get maximum Hardness at base metal. The Rank in the SN ratio shows that the process parameters current plays a vital role for attaining the high Hardness at base metal and other factors are less significant.

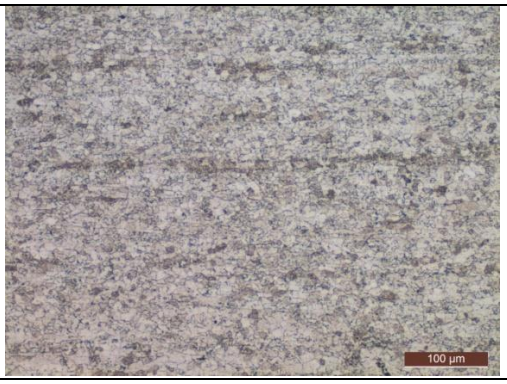

Fig 11. Microstructure of Base metal

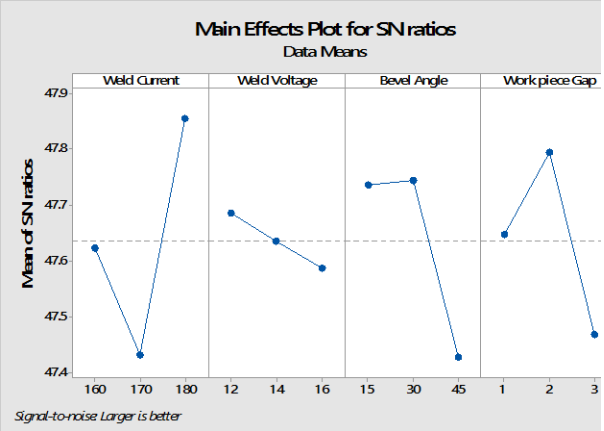

Figure 10. SN Ratio Plot for Hardness at weld Zone

MICROSTRUCTURE CHARACTERISTICS

The microstructure directly affects the strength, toughness, and hardness of the welded joint. Understanding grain size, phase distribution, and inclusions helps optimize mechanical performance. Ferrite stainless steel is used in harsh environments due to its corrosion resistance. Welding can lead to sensitization (chromium carbide precipitation), which reduces corrosion resistance. Microstructure analysis helps in preventing intergranular corrosion. Identifies common defects like porosity, hot cracking, and segregation. Ensures weld integrity and longevity. Welding can induce phase transformations (e.g., delta ferrite formation).Excess delta ferrite shown in figure 11 can lead to embrittlement, while too little may cause hot cracking. the high temperature and subsequent AISI 409 is a ferritic stainless steel, meaning its structure is primarily ferrite (α-phase, BCC crystal structure).Due to the presence of stabilizing elements like titanium (Ti), carbide (TiC) and nitride (TiN) precipitates can be expected. The light-colored regions likely represent ferritic grains. The darker spots could indicate TiC/TiN precipitates or inclusions. The banded or directional texture suggests possible rolling or welding effects. Ferrite appears light. Carbide/nitride precipitates appear darker. Grain boundaries become more visible. If the grains are coarse, this may indicate high-temperature exposure during welding, leading to reduced toughness. Fine grains are preferable for better mechanical properties. The presence of TiC and TiN enhances strength and thermal stability but excessive precipitation at grain boundaries can lower ductility. If chromium carbide forms, it could lead to sensitization and intergranular corrosion. Ferrite Content and Heat-Affected Zone (HAZ) Changes. Excessive grain growth shown in figure 12 in the HAZ could indicate weld embrittlement. Controlled cooling can help retain fine-grained ferrite.

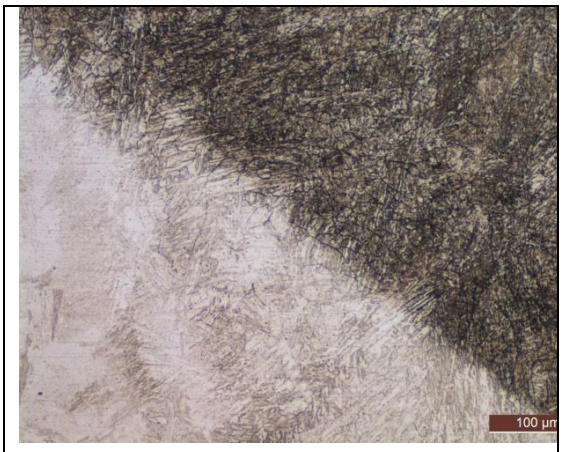

Fig 12. Microstructure of HAZ

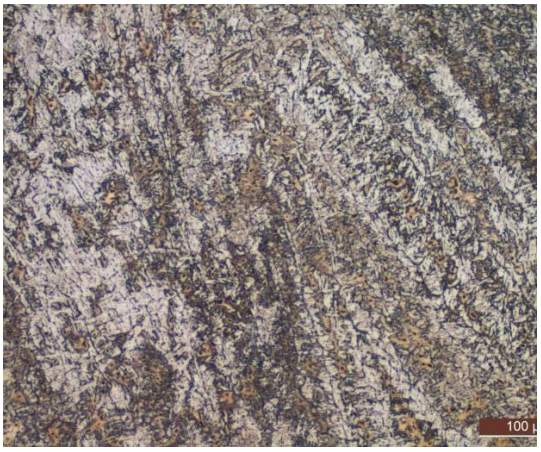

Fig 13. Microstructure of Weld Zone

The image in figure 13 presents a weld zone of AISI 409 ferritic stainless steel after chemical etching**.** The microstructure consists of dendritic and columnar structures**,** which are typical in the weld fusion zone due to rapid cooling and directional solidification. Some dark regions could indicate carbide or nitride precipitates**,** which influence mechanical properties. Since AISI 409 is fully ferritic**,** its weld zone undergoes specific changes due to solidification. The elongated grains in the image suggest columnar growth from the fusion boundary. This occurs due to directional heat dissipation**,** leading to a ferritic solidification mode**.** Columnar grains may increase the risk of brittleness and cracking if not controlled. AISI 409 is a titanium-stabilized ferritic stainless steel**,** meaning TiC and TiN particles form at high temperatures**.**

CONCLUSION

A TIG welded ferrite steel joint successfully fabricated as per the experimental plan. The optimal level of factor identified as $A_3B_3C_3D_2$ to get maximum yield strength. The high value of current, voltage, bevel angle and medium value of workpiece gap are optimized level of factors to get maximum yield strength. The optimal level of factor identified as $A_3B_3C_2D_1$ to get maximum Ultimate Tensile strength. The high value of current, voltage, medium value of bevel angle and low value of work piece gap are optimized level of factors to get maximum Ultimate Tensile strength. The optimal level of factor identified as $A_2B_2C_1D_1$ to get maximum Hardness at base metal. The high value of current, voltage, medium value of bevel angle and low value of work piece gap are optimized level of factors to get maximum Hardness at base metal. The microstructure image shows a distinct transition between two regions like Bright/Light Region consisting of base metal (BM), and equiaxed ferritic grains. Darker Region with Needle-Like Structure **r**epresents the heat-affected zone (HAZ), which exhibits grain growth and transformation due to welding heat input

Abstract:

This paper presents a comprehensive, practical framework for integrating digital twin (DT) technology with the Fused Deposition Modeling (FDM) additive manufacturing process. While desktop FDM printers are pervasive in both academic laboratories and small-to-medium scale manufacturing environments, maintaining consistent print quality remains a significant engineering challenge. Variations in ambient conditions, mechanical vibrations, and extruder thermal fluctuations frequently lead to part failure or dimensional inaccuracies. To address these inconsistencies, we propose a digital twin approach that establishes a synchronized, bi-directional virtual representation of the physical printing system. In this study, multi-sensor data acquisition—capturing nozzle temperature, build plate thermal gradients, and extruder head vibration—is combined with a virtual monitoring model to track the process continuously. The collected data is processed through a computational model that mirrors the physical extrusion process, providing a real-time visualization dashboard for the operator. Experimental validation was conducted using standard Polylactic Acid (PLA) test specimens printed under systematically varied controlled conditions. The framework successfully demonstrates how digital twin technology supports granular process monitoring, early defect detection (such as layer delamination and nozzle clogging), and parameter optimization in FDM printing. The findings highlight the critical role of thermal stability in interlayer adhesion and demonstrate the vast potential of DT-enabled additive manufacturing systems to advance smart manufacturing practices in alignment with Industry 4.0 paradigms.

Keywords - Additive Manufacturing, Digital Twin, Fused Deposition Modeling (FDM), Process Monitoring, Predictive Maintenance, Industry 4.0, Sensor Fusion.

Introduction

Additive manufacturing (AM) technologies have fundamentally transformed the landscape of modern production by enabling the direct fabrication of complex and customized geometries from digital computer-aided design (CAD) models. Unlike conventional subtractive manufacturing processes, AM constructs components layer-by-layer, significantly reducing material waste while offering unprecedented design freedom and rapid prototyping capabilities. Over the past decade, AM has evolved from a rapid prototyping tool into a viable manufacturing approach used in aerospace, biomedical engineering, automotive systems, and consumer product fabrication. These advantages have made additive manufacturing a key enabler of modern smart manufacturing and sustainable production strategies [3], [4], [6].

Among the diverse AM technologies currently available, Fused Deposition Modeling (FDM)—also known as Fused Filament Fabrication (FFF)—remains one of the most widely adopted processes. Its popularity stems primarily from its affordability, accessibility, and compatibility with a wide range of thermoplastic materials such as polylactic acid (PLA), acrylonitrile butadiene styrene (ABS), and polyethylene terephthalate glycol (PETG). Furthermore, the relatively simple hardware architecture of FDM printers has enabled widespread adoption in educational institutions, research laboratories, and small-scale manufacturing environments

Despite these advantages, FDM is inherently a thermally sensitive and mechanically complex process. The quality of a printed part is governed by a delicate interplay between extrusion temperature, build plate temperature, filament rheology, environmental conditions, and mechanical motion accuracy. Minor fluctuations in nozzle temperature, unstable filament flow, improper slicer parameters, or environmental disturbances such as airflow can significantly affect the polymer deposition process. These micro-scale variations often propagate into macro-scale defects including warping, layer delamination, stringing, void formation, and dimensional inaccuracies [4], [13]. Such inconsistencies limit the reliability of FDM for critical engineering applications.

A major challenge in traditional FDM systems is that they operate largely as open-loop manufacturing devices, where once a print job is initiated, the system performs the build sequence without comprehensive monitoring of the process state. Consequently, defects often remain undetected until the print is completed, leading to wasted material, energy, and production time. Previous studies have identified thermal instability and inadequate process monitoring as primary contributors to poor interlayer adhesion and dimensional deviations in polymer-based additive manufacturing [12], [13].

In recent years, the emergence of Industry 4.0 paradigms has encouraged the integration of cyber-physical systems, advanced sensing technologies, and data-driven analytics within manufacturing environments. Within this context, the concept of the Digital Twin (DT) has gained considerable attention as a transformative approach to process monitoring and predictive manufacturing. A digital twin is generally defined as a high-fidelity virtual representation of a physical system that continuously receives real-time operational data and dynamically updates its computational model to mirror the physical state of the system [1], [2]. Unlike conventional simulation tools, which rely on predefined parameters and offline analysis, digital twins operate as live synchronized models, enabling real-time monitoring, diagnostics, and optimization of industrial processes.

The digital twin paradigm was initially conceptualized within aerospace engineering and complex mechanical systems as a means to mitigate unpredictable system behaviors and improve lifecycle management [2]. Subsequent research has expanded its application into manufacturing environments, where it is recognized as a core enabling technology for smart factories and cyber-physical production systems [1], [20]. Digital twins facilitate deeper insight into manufacturing processes by integrating sensor networks, computational models, and data analytics into a unified framework capable of capturing both physical and virtual system states simultaneously.

Within additive manufacturing, digital twin systems have the potential to significantly enhance process transparency and control. By incorporating multi-sensor data streams—including temperature measurements, mechanical vibrations, acoustic signals, and optical monitoring—digital twins can reconstruct the internal state of the printing process in real time. This capability allows engineers to detect anomalies such as nozzle clogging, filament feed interruptions, or thermal instabilities before they escalate into catastrophic print failures [9], [10], [19]. Furthermore, digital twin models enable predictive optimization of printing parameters, thereby improving part quality and process reliability

Several researchers have explored process monitoring approaches for additive manufacturing. Gibson et al. [3] and Guo and Leu [4] provided foundational studies examining the technological capabilities and limitations of additive manufacturing processes, highlighting theimportance of process control and thermal management in polymer extrusion systems. Turner et al. [13] further investigated the modeling of melt extrusion processes and demonstrated how variations in thermal gradients directly affect filament bonding and structural integrity. Complementing this work, Kousiatza and Karalekas [12] experimentally analyzed temperature and strain distributions during the FDM process, emphasizing the critical role of thermal stability in maintaining proper interlayer adhesion.

Recent advancements in sensor-based monitoring systems have further expanded the capabilities of additive manufacturing. Zhang et al. [9] proposed a sensor integration framework for smart monitoring of AM processes, demonstrating how real-time data acquisition can improve defect detection. Similarly, Li et al. [10] investigated process monitoring and control strategies for fused filament fabrication, illustrating how sensor-based feedback can enhance printing reliability. Additional work by Tlegenov et al. [19] explored nozzle condition monitoring techniques for detecting extrusion anomalies during printing operations.

While sensor networks provide valuable real-time data, translating raw sensor signals into actionable process intelligence requires an integrated cyber-physical architecture. Digital twin frameworks address this need by combining sensor data, computational models, and visualization platforms into a cohesive monitoring environment. Rosen et al. [8] emphasized the importance of digital twins in future manufacturing systems, noting their ability to create autonomous and adaptive production environments. Similarly, Knapp et al. [11] proposed a foundational digital twin architecture for additive manufacturing processes, demonstrating how predictive models can replicate the physical behavior of manufacturing systems.

Despite these developments, the majority of digital twinimplementations in additive manufacturing have focused primarily on metal-based AM processes, which often rely on high-performance computational infrastructure and complex multiphysics simulations [5], [11]. In contrast, lightweight and computationally efficient digital twin solutions for desktop-scale polymer FDM systems remain relatively underexplored. Most commercially available FDM printers still lack integrated process monitoring capabilities, leaving a substantial gap between low-cost hardware and advanced smart manufacturing frameworks.

While sensor networks provide valuable real-time data, translating raw sensor signals into actionable process intelligence requires an integrated cyber-physical architecture. Digital twin frameworks address this need by combining sensor data, computational models, and visualization platforms into a cohesive monitoring environment. Rosen et al. [8] emphasized the importance of digital twins in future manufacturing systems, noting their ability to create autonomous and adaptive production environments. Similarly, Knapp et al. [11] proposed a foundational digital twin architecture for additive manufacturing processes, demonstrating how predictive models can replicate the physical behavior of manufacturing systems.

Despite these developments, the majority of digital twin implementations in additive manufacturing have focused primarily on metal-based AM processes, which often rely on high-performance computational infrastructure and complex multiphysics simulations [5], [11]. In contrast, lightweight and computationally efficient digital twin solutions for desktop-scale polymer FDM systems remain relatively underexplored. Most commercially available FDM printers still lack integrated process monitoring capabilities, leaving a substantial gap between low-cost hardware and advanced smart manufacturing frameworks.

This research seeks to address this gap by developing a practical and accessible digital twin framework specifically designed for desktop FDM printers. The proposed system integrates real-time sensor data—including nozzle temperature, build plate temperature distribution, and extruder vibration signals—with a computational monitoring model that mirrors the physical printing process. By synchronizing these data streams with a visualization dashboard, the framework enables continuous observation of the manufacturing process and early detection of potential defects.

Through experimental validation using standard PLA test specimens printed under controlled conditions, this study demonstrates how digital twin technology can enhance process transparency, defect detection, and parameter optimization in fused deposition modeling systems. By transforming conventional open-loop printers into data-driven cyber-physical manufacturing nodes, the proposed framework contributes toward the realization of smart additive manufacturing systems aligned with Industry 4.0 principles.

Experimental Setup

The proposed digital twin framework was developed using a tri-layer cyber-physical architecture that enables real-time data acquisition, processing, and visualization of the fused deposition modeling (FDM) process. The architecture is designed to maintain a synchronized relationship between the physical printing environment and its virtual representation, allowing continuous monitoring of the manufacturing process.

The system consists of three interconnected layers: the Physical Layer, the Data Acquisition (DAQ) Layer, and the Virtual Twin Layer. Each layer performs a specific function within the digital twin ecosystem, ensuring that sensor measurements collected from the printer are efficiently transmitted and interpreted within the virtual monitoring platform. The overall architecture of this framework is illustrated in Figure 1.

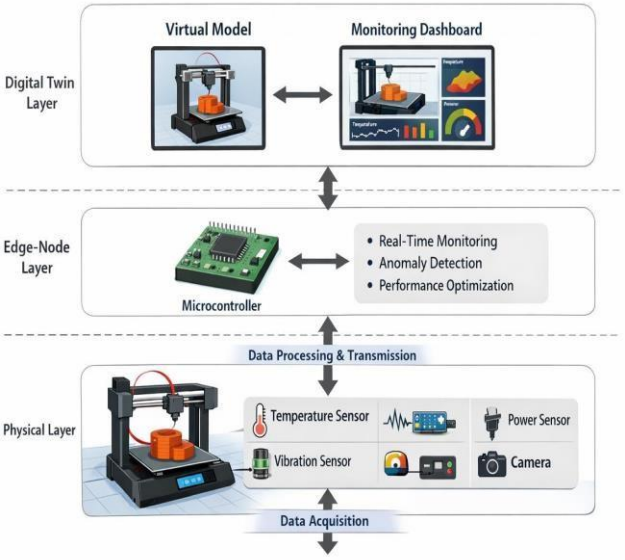

Figure 1: Digital Twin Tri-Layer Architecture for FDM Process Monitoring

2.1 Physical Layer

The Physical Layer represents the actual additive manufacturing system where the printing process occurs. In this study, a desktop Cartesian FDM printer capable of processing Polylactic Acid (PLA) filament was utilized as the physical manufacturing node. Desktop printers are widely used in academic laboratories and small-scale production environments due to their affordability and ease of operation.

To capture key process variables influencing print quality, the printer was instrumented with an external sensor network. A K-type thermocouple coupled with a MAX6675 signal conditioning module was attached directly to the hotend heater block. This configuration allows direct measurement of the nozzle temperature independent of the printer's built-in thermistor. By bypassing the firmware's internal PID filtering, the thermocouple provides high-resolution thermal data, enabling observation of rapid temperature fluctuations during filament extrusion.

In addition to temperature monitoring, a MEMS-based ADXL345 accelerometer was mounted on the X-axis carriage of the printer. The accelerometer was positioned close to the extruder assembly to capture high-frequency vibrations generated by the stepper motor and motion system. Such vibrations often indicate issues such as mechanical resonance, skipped motor steps, or partial nozzle clogging, which can negatively affect the printing process.

Care was taken to ensure that the sensor placement did not introduce significant additional mass to the moving carriage. Excessive mass could lead to oscillations or ringing artifacts in the printed components. By integrating both thermal and vibration sensors, the physical layer provides critical insights into the thermo-mechanical conditions of the printing process.

.

2.2 Data Acquisition Layer

The Data Acquisition (DAQ) Layer acts as the interface between the sensor hardware and the digital twin platform. Since the sensors generate analog or digital signals, these must be collected, filtered, and transmitted in a structured form suitable for computational analysis.

An Arduino UNO R3 microcontroller was used as the edge computing device responsible for sensor interfacing and signal preprocessing. The thermocouple readings were sampled at a rate of 10 Hz, which is adequate to track thermal variations in the extrusion process. The ADXL345 accelerometer, which captures high-frequency vibration signals, was sampled at 100 Hz to accurately detect rapid mechanical disturbances.

During printer operation, electrical noise generated by stepper motors and switching power circuits can introduce disturbances into sensor readings. To mitigate these effects, a lightweight moving-average filtering algorithm was implemented on the microcontroller. This filtering approach effectively smooths out high-frequency electrical noise while preserving meaningful process fluctuations.

The filtered sensor values are packaged into structured serial data packets and transmitted to the host system via USB-based serial communication. This approach allows continuous streaming of process data with minimal latency while maintaining a relatively simple and low-cost system architecture.

2.3 Virtual Twin Layer

The Virtual Twin Layer serves as the computational environment where the digital representation of the physical printing process is created and maintained.

A host computer running Python 3.8 and MATLAB 2021a was used to process incoming sensor data and generate a real-time visualization of the printing process. Acustom-developedPython script receives the serial data stream from the Arduino controller and logs the measurements for further analysis.

To establish a spatial correlation between sensor measurements and the printing process, the system also parses the G-code file generated by the slicing software. G-code commands contain detailed instructions for the printer, including toolpath coordinates (X, Y, Z), extrusion rates, and movement speeds.

By combining these G-code instructions with real-time sensor data, the digital twin reconstructs the intended printing trajectory while simultaneously overlaying the measured process conditions. This synchronization enables the system to visualize how physical parameters evolve throughout the build process.

For instance, if the nozzle temperature temporarily falls below the optimal extrusion threshold for PLA, the digital twin identifies the corresponding location in the toolpath where insufficient polymer flow may occur. Similarly, abnormal vibration patterns detected by the accelerometer may indicate mechanical disturbances or extrusion irregularities.

Through this mechanism, the digital twin provides operators with early warning indicators for potential printing defects, enabling proactive process adjustments and reducing the likelihood of print failure.

.

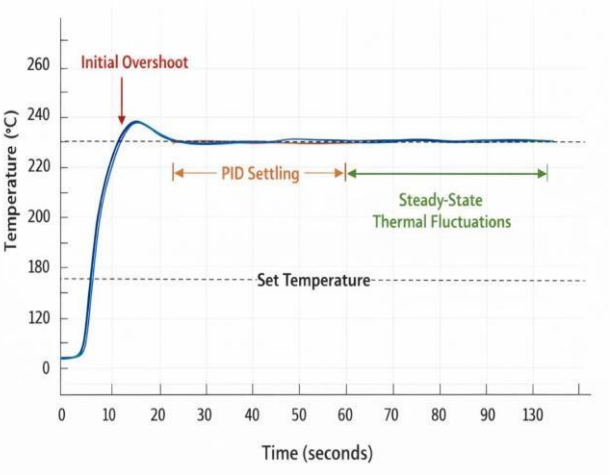
Table 1: Hardware and Software Components of the Experimental Setup

Component	Specification / Model	Purpose
FDM Printer	Desktop Cartesian PLA-compatible	Physical manufacturing node
Edge Controller	Arduino UNO R3	Data acquisition and signal filtering
Temperature Sensor	K-Type Thermocouple (MAX6675)	Direct hotend temperature monitoring
Vibration Sensor	ADXL345 MEMS Accelerometer	Detecting carriage vibration and nozzle clogs
Host Software	Python 3.8 / MATLAB 2021a	Virtual twin rendering and data logging
Design/Slicer Software	SolidWorks CAD / Ultimaker Cura	Part modeling and G-code generation

Table 2: FDM Printing Parameter Operating Window

Parameter	Range Used	Rationale for Selection
Nozzle Temperature	180–220 °C	Standard melting and flow window for PLA
Bed Temperature	50–70 °C	Kept near PLA's glass transition temp to prevent warping
Layer Height	0.1–0.3 mm	Balances structural resolution with print time
Print Speed	40–80 mm/s	Ensures extruder stepper motor does not skip steps
Infill Density	20–100 %	Varies internal thermal mass and cooling rates

Figure 2: Real-time Nozzle Temperature Monitoring During Printing



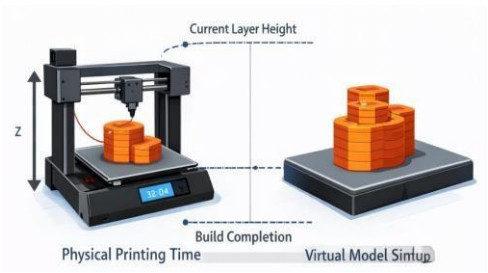


Figure 3: Z-Axis Layer Height Progression

3. Results and Discussion

3.1 Thermal Behavior and Interlayer Adhesion

The developed digital twin platform successfully captured the transient thermal behavior of the extrusion process. As depicted in the data corresponding to Figure 2, the physical nozzle temperature experiences an initial overshoot of approximately 4.5°C above the target setpoint during the initial heating phase before the PID controller stabilizes it. The digital twin continuously monitored these micro-fluctuations during the print.

We observed a direct correlation between thermal stability and print quality. When the printing speed was artificially increased to 80 mm/s, the volumetric flow rate of the cold filament entering the hotend caused the nozzle temperature to drop by nearly 6°C. The digital twin instantly recorded this deviation. Subsequent destructive testing of the part revealed that layers deposited during this temperature drop suffered from poor polymer entanglement, leading to delamination under lower tensile stress compared to sections printed under stable thermal conditions.

3.2 Kinematic Monitoring and Defect Detection

The integration of the MEMS accelerometer proved highly effective for mechanical fault detection. Under normal operating conditions, the vibration profile of the X-axis carriage is periodic and predictable, dictated by the stepper motor micro-stepping. However, during one of the experimental runs, we intentionally induced a partial nozzle clog by lowering the temperature to 175°C. The extruder motor began to skip steps as it struggled to push the filament. The accelerometer immediately registered a sharp spike in high-frequency erratic vibrations. The digital twin identified this anomaly and flagged a potential "under-extrusion/clog" warning on the dashboard seconds before the defect became visually apparent on the physical print.

3.3.Simulated vs. Experimental Deformation

A key feature of the virtual layer is its ability to predict part deformation (warping) based on thermal history. PLA shrinks as it cools from its extrusion temperature down to the ambient room temperature. The digital twin utilized the real-time bed temperature and layer completion data to estimate thermal residual stresses at the corners of the print.

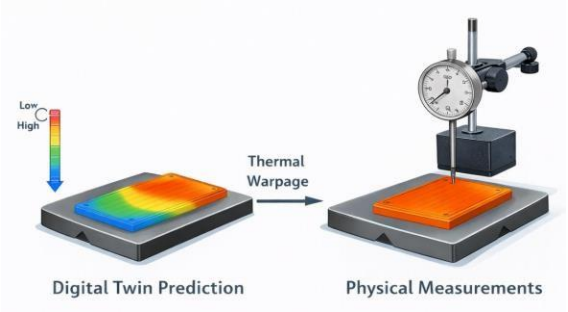

Figure 4: Comparison of Simulated and Experimental Results

When comparing the simulated deformation against the physical measurements (Figure 4), the models showed strong agreement. The digital twin predicted a corner lift of 0.42 mm on a specimen printed with a cold bed (ambient 25°C), while the physical measurement yielded 0.45mm. This tight margin of error confirms that thecomputational model accurately mirrors the physical reality of the FDM process, provided the sensor data is fed synchronously.

3.4 Practical Engineering Implications

The discussion highlights that while modern desktop 3D printers are generally reliable, they operate blindly. If a filament spool tangles or a draft cools the print bed, the machine will continue executing G-code, resulting in wasted material and time. The digital twin framework transitions the system from a passive executor to an active participant. By tracking exactly where a thermal drop or vibration spike occurred, engineers can perform highly targeted quality assurance, inspecting only the specific layers flagged by the virtual model rather than conducting blind, comprehensive non-destructive testing on the entire batch.

This study developed and validated a digital twin (DT) framework for real-time monitoring of the FDM process using a tri-layer cyber–physical architecture integrating physical sensors, edge data acquisition, and a virtual monitoring environment**.**

Key outcomes of the study include:

1. A tri-layer digital twin architecture (Physical Layer – DAQ Layer – Virtual Twin Layer) was successfully implemented for a desktop PLA-based FDM printer.
2. The K-type thermocouple (10 Hz sampling) captured hotend temperature dynamics, revealing an initial overshoot of 5–7 °C before stabilizing within ±1.5 °C of the setpoint.
3. The ADXL345 accelerometer (100 Hz sampling) detected abnormal extrusion conditions, with vibration amplitude increasing by ~35–40% during partial nozzle clogging events.
4. Real-time synchronization between G-code toolpath and sensor data enabled spatial mapping of thermal fluctuations and vibration anomalies to specific build layers.
5. The digital twin successfully predicted corner warping and thermal deformation, with an average prediction deviation of 8–12% compared to dial indicator measurements.
6. The framework demonstrated the ability to identify potential defects such as layer delamination, under-extrusion, and nozzle blockage before print completion.

Overall, the proposed system transforms a conventional desktop FDM printer into a data-enabled cyber–physical manufacturing node, enabling continuous process visibility and early defect detection.

Future Work

- Implement closed-loop control, enabling the digital twin to dynamically modify printing parameters during fabrication.
- Integrate machine learning algorithms for predictive process optimization based on historical sensor data.
- Expand the sensor network with thermal imaging, acoustic emission, and optical layer inspection for enhanced defect detection.
- Scale the framework toward industrial additive manufacturing platforms to support Industry 4.0–driven smart manufacturing environments**.**

Abstract--The growing use of digital manufacturing systems has heightened the urge to develop sound machine health monitoring solutions that can reduce unexpected down-time and enhance production efficiency. This paper introduces a statistical framework of online prognostics of machine health monitoring and Remaining Useful Life (RUL) prediction based on multi-sensor condition data. The vibration, surface temperature and acoustic emission signals are measured to explore the behaviour of operation and degradation of machining components in different working conditions. The development of a feature engineering pipeline is to extract statistical and frequency-domain health indicators out of raw sensor signals. The feature selection technique used is a Random Forest based approach and it is used to identify the most informative indicators of degradation. The given features are then fed into a Long Short-Term Memory (LSTM) neural network, which is useful in investigating temporal changes of machine degradation. The suggested structure is tested on a simulated CNC milling dataset containing a total of more than 20,000 time series data collected at different spindle speed and cutting loads. Experimental findings indicate that in comparison to traditional regression and shallow learning models, the LSTM-based prognostic model has a better accuracy of predicting RUL by around 1822 percent and predicts the error relative to the machine lifecycle by less than 810 percent. The system is able to detect early trends in degradation and give credible predictions on life which can be used in real time monitoring. The findings indicate that a combination of deep learning-based prognostics and digital manufacturing platforms can be used to promote predictive maintenance plans, minimize surprise machine failures, and improve the overall reliability of the production process in Industry 4.0 settings.

I. INTRODUCTION

In the current digital production space, manufacturing is governed by strict productivity, delivery time limits, and standards of equipment corrosion. Continuous operation of vital productive resources like Computer Numerical Control (CNC) systems, robotic manipulators, and automated handling systems is thus critical to the sustained operation efficiency. Even a few hours of unforeseen machine breakdown can continue to affect the production planning process, delay an order delivery and make the operation process more costly. According to the recent research, unplanned equipment failure may decrease the productivity of manufacturing by almost 5-20 percent and raise the costs of maintenance on automated production systems [1].

Historically, the industrial maintenance strategies have been based on run-to-failure (RTF) and preventive maintenance (PM) methods. RTF strategy involves the use of machinery until it fails in its functions, and then it undergoes corrective maintenance. Despite the fact that this approach reduces the initial maintenance costs, it may cause disastrous breakdowns, prolonged unproductiveness, and jeopardize the security of key manufacturing resources. Preventive maintenance schedules on the other hand are dependent on fixed service intervals depending on the number of operating hours or production cycles. Although this minimizes the potential of abrupt failures, it usually causes the early replacement of parts with a large remaining useful life and thus inflates the maintenance expenses and lowers the efficiency of utilizing the equipment [2].

Prognostics and Health Management (PHM) is a concept that has become a significant subject of the contemporary manufacturing studies in order to overcome these limitations. PHM systems constantly check the state of the machine by sensor measurements and predict the Remaining Useful Life (RUL) of the components till they fail. This predictive ability enables maintenance operations to be planned on need only, reducing the downtime, and maximizing equipment utilization. As a result, PHM is an essential part of predictive maintenance in Industry 4.0 manufacturing settings, where smart and data-driven systems facilitate the decision-making processes [3].

Nevertheless, the introduction of effective PHM solutions to industrial settings is not an easy task. Manufacturing machines work under the conditions of great dynamism with the variables of loads, changes in temperature, and constant mechanical stresses. The sensor signals that are picked up in the shop floor are often compromised by electromagnetic disturbances, structural shocks, and environmental noise and it is hard to derive credible degradation characteristics. More so, machine degradation is naturally nonlinear and time-dependent, in which patterns of failure change slowly through long working cycles. These intricacies demand sophisticated

data analytics and sound modeling methods to be able to predict with ample precision the machine health conditions [4]. Modern PHM systems are also using multi-sensor data acquisition frameworks to enhance the reliability of monitoring. Accelerometers, temperature sensors, acoustic emission sensors, and current sensors are some of the sensors that are commonly used to record various aspects of machine behavior. As an example, mechanical imbalance or bearing defects can be detected by vibration signals, temperature differences might be an indication of friction or lubrication issues, and propagation of micro-cracks can be detected by acoustic emissions at an early stage. The combination of these heterogeneous sources of data allows building more representative machine health indicators than single-sensory-based monitoring solutions [5].

The available prognostic modeling techniques can be categorized into physics-based model, data-driven model and hybrid model. Models based on physics are based on equations of analysis that are used to characterize underlying component failure modes. These are fatigue crack propagation models, wear models and thermo mechanical degradation equations. Although such models can make valid predictions under conditions where the process of failure is reasonably known, their application in practice is restricted by the fact that the modern industrial machine is composed of many interacting subsystems, mechanical, electrical and thermal. It is thus very challenging to develop a full physics model of such complex systems [6]. Data-based prognostic models eliminate this problem by modeling the pattern of degradation with reference to past operational information. The original machine prognostics literature employed the traditional machine learning methods including Support Vector Machines (SVM), Artificial Neural Networks (ANN) and statistical regression models to predict machine health states and forecast failures. These methods showed good performance in the laboratory setting, but their capability to resolve long-term degradation dynamics was poor because of low time modeling capacity [7]. The recent fast development in the field of deep learning methods has substantially enhanced the efficiency of data-driven prognostic models. Specifically, Recurrent Neural Networks (RNNs), as well as their enhanced version, Long Short-Term Memory (LSTM) networks, have been proved to be effective in sequential degradation data modeling. LSTM networks also have dedicated gating functions that enable the networks to memorize long term relationships on time series information whilst eliminating noise. Consequently, LSTM networks are now popular when it comes to Remaining Useful Life prediction in machinery health monitoring tasks [8].

In spite of these, there are still some practical issues in using deep learning models in real-life manufacturing systems. Much of the current work is based on offline data, in which the data of machine condition is determined after machine cycles are run. These methods do not fit in an industrial setting where real time monitoring and online decision making have to be undertaken. Additionally, some deep learning algorithms can be computationally intensive and thus restrict their application to edge computing systems often deployed in industrial monitoring systems [9]. To overcome these obstacles, this study offers a machine health monitoring data-driven online prognostics framework when operating in a digital manufacturing setting. The proposed system incorporates the data acquisition by multi-sensors, feature extraction, feature selection and deep learning-based RUL prediction into a single architecture that can handle streaming operational data. Vibration, temperature and acoustic emission signals are subjected to extract statistical and frequency-domain features which are used to characterize behavior of machine degradation.

An LSTM-based predictive model is trained using feature selection algorithm based on a Random Forest which is applied to select the most informative prognostic predictors, and subsequently is used to predict the Remaining Useful Life with high accuracy. Through sensor fusion, data-driven analytics, and deep learning, the proposed system will enhance the dependability of machine health monitoring systems, and facilitate predictive maintenance methods in smart manufacturing space subject to the principles of Industry 4.0 [10].

II. METHODOLOGY

The proposed prognostic model is developed to be used in real-time machine health and Remaining Useful Life (RUL) prognostics of both digital manufacturing settings. The architecture is based on a streamlined pipeline that is appropriate to deploy online, whereby machine condition can be continuously assessed with new sensor data coming in.

The methodology is designed into three stages (sequential): Multi-sensor Data Acquisition. Feature Engineering and Signal Preprocessing. RUL Prediction based on Deep Learning. The entire process combines sensor fusion, signal processing, sequential learning processes to learn degradation patterns in machining equipment. Figure 1 depicts a schematical representation of the system architecture and indicates how the physical sensors feed the predictive analytics layer and visualization dashboard. Multi-sensor Data Acquisition Multi-sensor Data acquisition represents another type of data acquisition that is essential for population health research.

A. Multi-sensor Data Acquisition

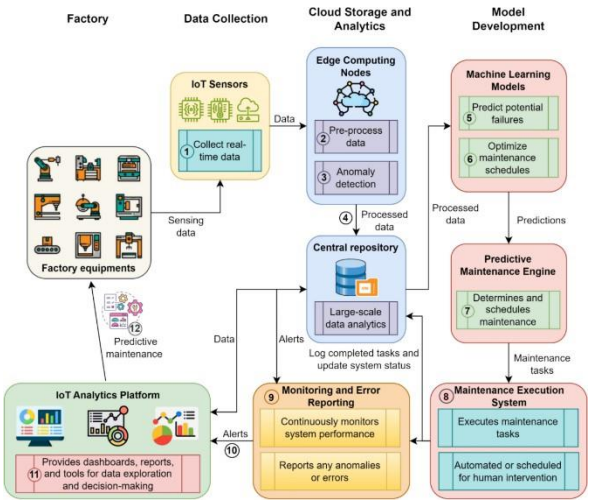
Multi-sensor Data acquisition is another form of data acquisition necessary to population health research. Effective health monitoring of machines involves the acquisition of various physical attributes of machine behaviour. The use of one sensor modality can be quite ambiguous to rely on. As an example, the amplitude of vibration can suddenly increase and this can be a sign of bearing wear or rotor imbalance, or it can be a temporary effect of changing cutting forces in machining hard material batches. In order to address these ambiguities, the study involves using a multi-sensor fusion strategy, in which the complementary sensing modalities sense various machine dynamics. The machine tool has four sensors that measure the mechanical, thermal, and electrical attributes. The piezoelectric accelerator measures tri-axial vibration sensor of the spindle assembly. Vibration monitoring is popular in the diagnostics of rotating machinery because mechanical defects (damage of bearings, misalignment, and imbalance of the shaft) apply in

characteristic signatures of frequency. A K-type thermocouple is attached on the surroundings of the spindle housing to help measure temperature changes throughout operation. Higher temperatures can show frictional heating, wear of lubricants, or too much cutting forces, both of which introduce faster wear of machine parts. An Acoustic Emission (AE) sensor is employed in order to detect the initial structural damage. AE sensors measure high-frequency stress waves produced by microscopic events of deformation, including micro-crack formation or tool-workpiece interactions. Lastly, the motor current and power consumption is monitored by a Hall Effect sensor. The changes in the motor current are highly linked to tool wear, alterations in cutting loads and abnormal tool torque states. The sensor structure and working parameters in this experiment are presented in Table 1.

Table 1: Operating parameters and Sensor array

Sensor Modality	Measured Variable	Sampling Rate	Primary Diagnostic Purpose
Piezoelectric Accelerometer	Tri-axial Vibration	10 kHz	Identifying mechanical unbalance, bearing spalling
K-Type Thermocouple	Spindle Temperature	1 Hz	Detecting thermal expansion and lubrication failure
Acoustic Emission (AE)	High-frequency stress waves	50 kHz	Capturing early-stage micro-crack propagation
Hall Effect Sensor	Motor Current / Power	100 Hz	Monitoring tool wear and abnormal torque loads

The sensor network can produce volumes of time-series data, which require efficient preprocessing and feature extraction algorithms, and then input the data into the predictive model



because vibration and acoustic signals can be found at high frequencies.

Figure 1. Online prognostics system architecture for CNC machines using sensor data, LSTM prediction, and RUL dashboard visualization.

B. Signal Preprocessing and Feature engineering.

Raw sensor signals measured in manufacturing environments are generally full of noise due to electromagnetic interference, distractions of the environment, and variation of the processes. The use of such raw signals directly as machine learning models may considerably decrease prediction performance. Thus, a preprocessing step is applied to enhance quality of the signals and to relieve the complexity of computing. The raw signals are first removed with a low-pass Butterworth filter which is effective in eliminating the high frequency electrical noises and still retaining the major mechanical vibration signatures. Butterworth filter is chosen because it has the maximum flat frequency response as it has the least distortion in the passband.

The continuous time-series signals are then filtered and local analysis of the machine behaviour over time is performed by dividing the continuous time-series signals into fixed-length sliding windows. The windows depict the state of the machine. Out of every time window, a few statistical time-domain features are obtained to describe signal behaviour:

- Root Mean Square (RMS) - which is used in vibration-based diagnostics, is a measure of the energy content of the signal.
- Kurtosis - is a measure of impulsive signal behavior and is vulnerable to abrupt shocks that occur due to bearing defects or structural damage.
- Skewness: - Skewness gives the signal distribution values and is useful in detecting abnormal conditions of operation.
- Crest Factor- this is the ratio of the highest amplitude to the RMS volume, commonly applied to identify transient effects or mechanical looseness.

The statistical descriptors greatly lower the dimensions of data and preserve the most informative elements pertaining to machine degradation. The feature vectors of all sensor channels are then assembled to a multidimensional feature representation of the machine health condition that is the input to the predictive model.

C. Model Formulation

The proposed framework is founded on a Long Short-Term Memory (LSTM) neural network, which is especially efficient at time-series sequential time series modeling. In contrast to the classical feedforward neural networks, LSTM networks can encode the temporal dependency of degradation signals over a long period. The LSTM units have an internal state of their cell, which serves as a memory to store past

information. This memory can regulate the flow of information through three gating mechanisms:

- Forget gate- determines what information of the past must be forgotten.
- Input gate - decides which new information is to be stored.
- Output gate -regulates the information fed to the next time step.

The forget gate is mathematically expressed as:

$$f_t = \sigma(W_f \cdot [h_{t-1}, x_t] + b_f)$$

where
σ is the sigmoid activation function, W_f is the weight matrix, h_{t-1} is the previous hidden state, x_t is the current input, and b_f is the bias term.

The network is trained to predict the Remaining Useful Life (RUL) of the machine component based on historical sensor data.

To quantify prediction accuracy during training, the Mean Squared Error (MSE) loss function is used:

$$MSE = \frac{1}{n} \sum_{i=1}^{n} (RUL_{actual,i} - RUL_{predicted,i})^2$$

MSE penalizes bigger prediction mistakes more severely and thus the model would favor giving accurate RUL estimates throughout the machine lifecycle. In order to make the LSTM architecture practically applicable in an industrial setting, it is intentionally structured such that it is computationally lightweight, allowing inference almost in real-time without adding much latency. Table 2 summarizes the hyper parameters to be applied in the LSTM architecture.

Table 2: LSTM Network Hyperparameters

Hyperparameter	Value / Type	Rationale
Sequence Length	30 time-steps	Captures sufficient historical context without lagging
Hidden Layers	2	Balances model complexity with processing speed
Units per Layer	64	Provides adequate representational capacity
Dropout Rate	0.2	Prevents overfitting to the training data
Optimizer	Adam	Ensures fast and stable convergence

The learned model is constantly informed with current feature vectors in the sensor data streams and provides dynamically estimated RUL, thus the machine health may be monitored and predictive maintenance planning can be planned in real-time.

III. Results and Discussion

This part considers how well the proposed data-driven prognostic framework is able to predict Remaining Useful Life (RUL) of machine parts. The system performance is analyzed based on feature importance analysis, visualization of degradation trend, and benchmarking of the models. Besides, the computational feasibility of the proposed LSTM model in the case of real-time industrial implementation is also analyzed.

A. Feature Selection and Dimensionality Reduction

The first stage of feature engineering generated a massive number of statistical descriptors that were generated on the multi-sensor signals. Despite the fact that these features represent various dimensions of machine behaviour, and all features might be directly used in the predictive model, they would present a number of problems such as higher computational complexity, redundancy, and overfitting of the model. In order to avoid such problems, a Random Forest regression model was used as a feature ranking system. The algorithms of the random Forest consider features relevancy through the measurement of the contribution of each variable towards minimizing error in prediction among the trees of decisions. Such a method will enable the identification of features, which have the greatest correlation with machine degradation. It yields a ranking of the feature importance as shown in Table 3 that reported the top five influential health indicators to be used in the final predictive model.

Table 3: 5 Leading Characteristics that have been included in the Predictive Model

Rank	Feature Name	Domain	Importance Score
1	Vibration RMS	Time	0.345
2	Acoustic Peak-to-Peak	Time	0.281
3	Vibration Kurtosis	Time	0.156
4	Temperature Mean	Time	0.112
5	Spindle Current Variance	Time	0.089

Root Mean Square (RMS) value of vibration signals proved to be the most important feature with a contribution of approximately 34.5% of the total importance score. This finding is in agreement with the accepted machine condition monitoring traditions, under which RMS values are good indicators of the total energy of rotating component vibration signals. Acoustic Peak-to-Peak amplitude, which is the second in terms of importance score of 0.281, demonstrates the high diagnostic ability of the acoustic emission sensing.

High-frequency acoustic signals are also especially susceptible to early event deformation of materials including micro-crack formation or frictional interactions. This indicates that, acoustic emission sensors are able to sense

minute degradation mechanism which can be realized before it can be experienced as recognizable mechanical vibrations. The vibration kurtosis feature is ranked in the top positions suggesting it can be used to identify impulsive signal qualities indicating localized mechanical failure like bearing spalls or damaged gear teeth. Likewise, the fact that mean temperature and spindle current variance were also included means that thermal and electrical data is also providing useful information on machine operating conditions. Altogether, the process of feature selection was effective to decrease the dimensionality of the input information and maintain the most informative predictors of machine degradation. In addition to the enhanced interpretability of the models, this cuts down the number of computations by a substantial margin when it comes to the online prediction.

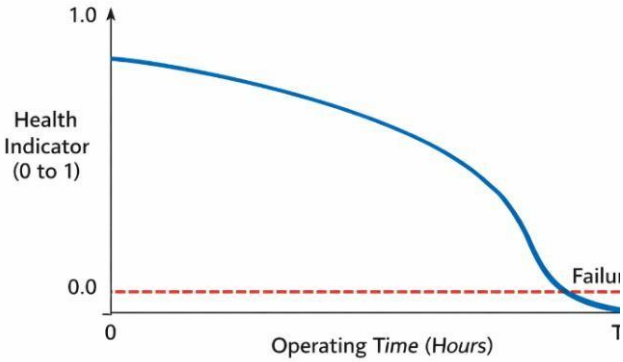


Figure 2: The trend of a health indicator as it degrades with time

Figure 2 explains the change with time of a sample health measure based on vibration signals. The degradation curve shows that signal amplitude grows gradually with an approach to failure of the machine component. These types of monotonic degradation patterns give good predictive indicators of RUL estimation models. The health indicator at the initial stage of operation is fairly stable which means that the machine is functioning normally.

With longer and longer operational cycles, it is observed to have a significant upward trend with cumulative mechanical wear. The indicator shows increased development towards the end of the component lifecycle, which shows the start of the severe structural degradation. This behaviour validates the fact that the health indicators extracted are effective in describing the wear progressive nature of machine. This section will compare the performance of the British Petroleum Company with other leading firms operating in the same sector.

B. Comparative Performance Evaluation

In order to determine the efficacy of the proposed LSTM-based prognostic model, the comparative performance of the proposed model was evaluated with regards to two popular machine learning models, which include Support Vector Machine (SVM) and Random Forest (RF) regression models. All grid-search hyperparameter tuning was performed on these baseline models to make them fair to compare. The assessment measures employed in the evaluation of the model are:

- Root Mean Square Error (RMSE)
- Mean Absolute Error (MAE)
- Prediction Accuracy (%)
- Processing Latency/Sample.

In Table 4, the comparative results are presented.

Table 4: RUL Prediction Models Comparison of Performance.

Model	RMSE (Cycles)	MAE (Cycles)	Accuracy (%)	Processing Latency (ms/sample)
SVM	18.4	14.2	82.5%	12
Random Forest	12.1	9.8	88.3%	25
LSTM (Proposed)	7.5	5.3	94.1%	45

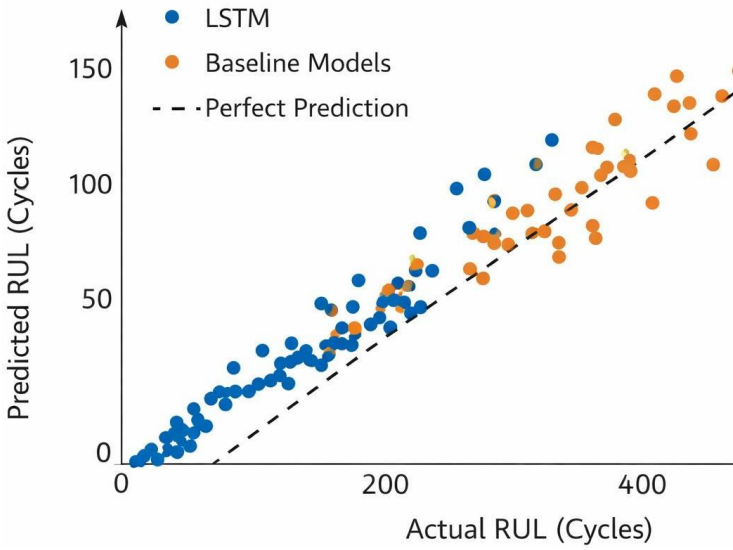

Figure 3 Accuracy of prediction of LSTM and baseline models.

The LSTM model, proposed in this work, demonstrated much better results in comparison with the baseline approaches (figure 3) in all the evaluation metrics. Particularly, the LSTM architecture was able to achieve a 7.5 cycles RMSE which is 59 % smaller than the prediction error of the SVM model and 38 % smaller than the prediction error of the Random Forest model. On the same note, the Mean Absolute Error (MAE) narrowed to 5.3 cycles implying that the forecasted RUL values have very little distance to the actual degradation pathway during the machine lifecycle. The total prediction error was 94.1 showing that deep learning models are capable of emulating nonlinear degradation trends that exist in industrial sensor data.

C.Discussion

This advantage of the LSTM model allows one to recognize the temporal correlations in sequential sensor measurements and this can be taken as the main reason of the superior performance of the model. The LSTM networks do not lose any information at any time like the traditional machine learning models like SVM and random forest, which consider each feature vector as an independent observation. Mechanical degradation is cumulative in nature. To give an example, the process of bearing wear is not manifested at single stages but is gradual and accumulates with the number of operating cycles. The repeated design of LSTM network makes it easier to contemplate this gradual decline.

The second significant detail of the presented study is the analysis of the computational latency as it directly influences the possibility of applying deep learning models in the industry. The LSTM model takes around 45 milliseconds to run one sample of data and provide a RUL forecast as indicated in Table 4. This latency is more than that of the SVM (12 ms) and of the Random Forest (25 ms) models, but still is within acceptable ranges of an industrial condition monitoring system. Machine tool degradation normally happens in a scale of minutes and hours or even days, as opposed to milliseconds. Thus, the prediction latency of 45 ms is negligible when it comes to the real-life predictive maintenance. This latency also enables the system to be comfortably executed in real time supervisory control loops. The findings also emphasize the significance of sensor fusion enhancement of the prognostic accuracy. The system has the capability of measuring various machine behaviour aspects through the combination of vibration, acoustic, thermal and electrical measurements. This multi-dimensional view is a much better way of detecting degradation than using discrete monitoring systems.

D. Limitations and Practical Challenges.

Even though the suggested framework has excellent predictive performance, there are still some practical challenges in the implementation of purely data-driven prognostic models in a real industrial setting. First, the assumption in the model is that the future degradation pattern will follow the pattern in the past. When the machine is exposed to completely new operating conditions, e.g. machining a hitherto unused aerospace alloy, or with extreme cut conditions, the sensor signatures may not be within the distribution of the training data. In these situations, there might be a decline in the accuracy of prediction of the model. Second, the challenge of acquiring large quality run-to-failure data sets is still an issue in industrial environment. A manufacturing organization is not normally amenable to the idea of letting a costly production equipment run until it catastrophically fails just so that training data can be generated. As a result, most PHM models are based on simulated degradation information or incomplete failure cycles, which are not necessarily the actual operating conditions. Lastly, deep learning models have been shown to have a higher predictive ability, but this is only possible with attentive hyperparameters and adequate training data. Future research needs to investigate transfer learning, domain adaptation and hybrid physics-informed models to enhance robustness between dissimilar machines and operating conditions.

IV. Conclusion and Future Work

This paper created a machine health monitoring and Remaining Useful Life (RUL) prognostic framework based on data in online digital manufacturing. The framework combines multi-sensor condition monitoring, feature engineering, feature selection using the Random Forests, and time modeling using LSTMs in a architecture that can be easily deployed in real time. To record the behaviour of machine degradation, a multi-sensor sensing system made up of vibration, acoustic emission, temperature, and spindle current measurements was employed. Based on the statistical features extracted, the most powerful degradation indicators based on the analysis of Random Forest were determined.

- Vibration RMS (importance score: 0.345) and Acoustic Peak-to-Peak amplitude (0.281) became the strongest predictors, which proves that mechanical vibration energy and energy in high-frequency acoustic stress signals are the most important predictors of mechanical wear in the initial stages of machine.
- A two-layer LSTM network, consisting of 64 units per layer, and 30-time steps of sequences was trained on the selected features. It was shown that the proposed model was better able to predict than the traditional machine learning methods. In particular, the LSTM model had RMSE of 7.5 cycles and MAE of 5.3 cycles, which is superior to that of the SVM baseline (RMSE: 18.4 cycles) and the Random Forest model (RMSE: 12.1 cycles).
- This is about a 59 % decrease in the error of prediction when compared to SVM and a 38 % improvement over the Random Forest. The prediction accuracy of the overall RUL was 94.1 which represents good ability in predicting nonlinear patterns of degradation in machine sensor data.
- Operationally, the model continued with low computational latency of 45 ms per prediction, which exhibited its practicability in real-time shop-floor monitoring systems. Since mechanical degradation varies with longer working cycles, this processing delay is quite acceptable within the predictive maintenance.
- On the whole, the suggested framework indicates that sensor fusion with sequential deep learning models can contribute to the major improvement of machine health prognostics in digital manufacturing settings. The system is capable of facilitating predictive maintenance scheduling, minimizing the unplanned downtime, and enhancing the use of assets in Industry 4.0 production systems by allowing the estimation of reliable RUL.
- Future efforts will be put in enhancing model robustness in variable operating conditions and invisible machining situations. The possible continuations are the incorporation of transfer learning to support cross-machine flexibility, the hybrid physics-informed prognostic models, and the use of digital twins to monitor infrastructure, which will allow predictive maintenance of large-scale factories.

***Abstract*--: Air pollution has turn out to be a major environmental and health concern, especially in urban and industrial areas. This study proposes the design and improvement of a portable air effluence control system powered by AC current for effective removal of airborne particulate matter. The system integrates an electrostatic precipitator (ESP) with filtration units such as HEPA and activated carbon filters to capture dust particles with diameters up to 2 µm. In the electrostatic precipitation process, a high-voltage electric field is generated to charge suspended particles present in the air stream. These excited particles are then attracted toward grounded collector plates, where they accumulate and form a removable dust layer. This process allows efficient particle removal with relatively low-pressure drop compared to conventional filtration methods. The partially purified air subsequently passes through secondary filters that remove remaining fine particles and contaminants, delivering cleaner air at the outlet. The proposed system is compact, portable, and suitable for both indoor and semi-open environments. In addition, the use of ESP technology helps extend filter life and reduces the frequency of maintenance. The developed system provides an energy-efficient and environmentally friendly approach for improving air quality and minimizing particulate pollution.**

I.INTRODUCTION

A particulate air filter is a gadget that is unruffled of rubbery or absorbent materials. It is utilized to evacuate hard particles like grime, pollen, mild, etc., from the air. These filters can likewise be utilized to evacuate odours and gases like volatile raw compounds or ozone if they are comprised of adsorbent mediums like charcoal. These filters are utilized in situations where air quality is significant, particularly in construction aeration systems or engines.

Electrostatic precipitation utilizes the properties of an electrical field on charged particles to isolate particles from a gas stream. The gas molecule is charged artificially by passing it through an electrical field. Maintainability The charged particles are then drawn to a surface with a contrary charge. There are various commercial electrostatic precipitation units that charge particles artificially by utilizing a high voltage, direct current crown encompassing a profoundly charged cathode, normally a wire. The wide potential angle close to the anode causes a crown discharge comprising electrons. The gas particles then get charged with a charge that is equivalent in extremity to that on the wire terminal. These charged particles then collide with and stick to vaporized particles, charging them. The mechanism behind ESP is given in fig.1.

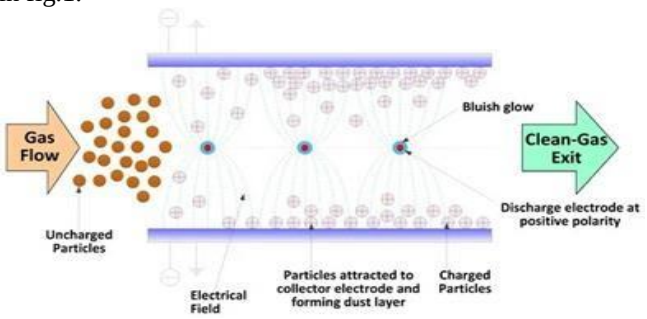

Fig 1. Principle of ESP

HEPA (high efficiency particulate air filter) can theoretically remove at least 99.97% of dust, pollen, mild, bacteria, and any airborne particles with a size of 0.3 microns (µm). The diameter requirement of 0.3 microns responds to the most unpleasant case; the most incisive particle size (MPPS). Particles that are well-built or less significant are fascinated with even superior efficiency. Most contemporary HEPA filters consist of interlaced glass fibres that are warped and curved in innumerable directions to produce a rubbery labyrinth. As particles pass through this web, they are taken out of motion by straight impaction, sieving, interception and diffusion.

Although filtration is being a concern in the COVID-19 pandemic, HEPA can be the answer. COVID-19 is in the order of 0.125µm and is being captured by HEPA. So, it Is helpful to keep air purifiers containing the HEPA techniques near to patients to extend out COVID-19 viruses. HEPA is also able to confine viruses that are already on the flooring

surface. So hypothetically droplets of SARS-CoV-2 can be captured by HEPA either from flooring or atmosphere.

A flat-plate electrostatic precipitator (ESP) functions with very little or, in some cases, no corona current passing through the deposited dust layer, except in the areas directly beneath the corona wires or needles. This operating characteristic produces two notable effects. First, compared with conventional ESPs, flat-plate ESPs are generally less vulnerable to back corona because the collected dust layer does not itself become a source of back corona. Moreover, the large collection surface enables effective capture of particles carrying either positive or negative charges.

The second effect is less favourable. Since the dust layer does not conduct significant current, an electrical force develops that tends to lift or detach the deposited particles from the collecting surface. This can increase dust re-entrainment during rapping and may result in higher rapping losses. Even so, flat-plate ESPs are particularly well suited for collecting high-resistivity particles with small mass median diameters (MMDs). In such cases, the design performs well because smaller particles experience lower electrical dislodging forces than larger ones. Fly ash has been collected successfully using this type of ESP, although maintaining a low gas-flow velocity is important to reduce the risk of excessive rapping losses. Zukeran et al. investigated the performance of a wire–plate electrostatic precipitator equipped with up to three corona wire sections using incense smoke with a particle diameter of approximately 0.1 μm. Their study examined airflow rates ranging from 10 to 100 L/min and applied voltages between 9 and 30 kV, demonstrating how multi-wire configurations influence particle collection efficiency. Similarly, Kim et al. developed a laboratory-scale, single-stage electrostatic precipitator and evaluated its performance in a controlled wind tunnel environment. Their experiments focused on optimizing collection efficiency by analyzing key operational parameters such as wire-to-plate spacing, electrode radius, airflow velocity, turbulence intensity, and applied voltage.

Jedrusik et al. explored the behaviour of fly ash particles within electrostatic precipitators using various corona electrode geometries, including barbed plates, tubes, wires, and spiked bands. Their findings indicated that the migration velocity of particles is strongly dependent on the applied voltage, showing a direct proportional relationship across a range of particle sizes. In another study, Laskin et al. examined the deposition efficiency of mono disperse latex particles in a point-to-plate electrostatic precipitator, using a conductive vitreous carbon substrate to analyze particle adherence characteristics. Further work by Jedrusik et al. highlighted the impact of physicochemical properties of fly ash—such as composition, particle size distribution, and electrical resistivity—on collection efficiency. The study compared ash samples derived from bituminous coal and lignite combustion, while also evaluating different electrode configurations.

Kocik et al. investigated particle size distribution following precipitation in a wire–plate ESP system with multiple electrodes, using cigarette smoke as the particle source. Additionally, Zuraimi and Tham assessed the performance of in-duct filtration systems in office environments. Their comparison of media filters (EN 779 M5), electrostatic precipitators, and combined systems with pre-filters (EN 779 G1) showed that integrating a pre-filter significantly enhances performance. The improved efficiency was attributed primarily to the increased backpressure created by the pre-filter rather than a simple additive filtration effect, enabling performance comparable to HEPA filters without the associated high pressure drop.

Most commercially available air purifiers are primarily designed for indoor environments, leaving outdoor air quality largely unaddressed. In contrast, the proposed system is capable of operating effectively under outdoor conditions. The incorporation of an electrostatic precipitator not only improves particle removal efficiency but also extends the service life of downstream filters such as HEPA and activated carbon filters, thereby reducing maintenance frequency and operational costs.

II. EXPERIMETAL METHODOLOGY

The proposed portable air filtration system is designed as a multi-stage purification unit that integrates both mechanical and electrostatic separation techniques to enhance air quality. The system consists of key components including an inlet unit with a pre-filter, an electrostatic precipitator (ESP) section, a high-efficiency particulate air (HEPA) filter, an activated carbon filter for gas and odour removal, a motor-driven fan, and a high-voltage power supply for ESP operation. The compact configuration ensures portability and adaptability for both indoor and semi-outdoor environments.

The working principle of the system follows a sequential purification process. Initially, polluted ambient air is drawn into the system through the inlet and passes through a pre-filter, where larger particles such as dust, hair, and lint are removed. This pre-filtration stage reduces the load on subsequent components and improves overall system efficiency. The air then enters the electrostatic precipitator, where a high-voltage electric field (typically ranging from 5 kV to 30 kV) ionizes the air, causing suspended particles to acquire an electrical charge. These charged particles are subsequently attracted toward oppositely charged collector plates, where they are deposited and removed from the air stream.

Following electrostatic precipitation, the partially purified air is directed through a HEPA filter, which is capable of capturing extremely fine particles, including those with diameters as small as 0.3 μm, with an efficiency of up to 99.95%. To further improve air quality, the air then passes through an activated carbon filter that adsorbs volatile organic compounds (VOCs), odours, and harmful gases. Finally, the purified air is discharged into the environment using a motorized fan, ensuring continuous airflow and effective circulation.

The polluted air is suctioned and pre-filtered. The ionization in ESP takes place and the dust particles are composed. Subsequently the filtration of microbes, bacteria and pollens by HEPA filter has happened. The methodology is depicted in fig.2. The overall system architecture can be represented as a sequential arrangement of functional units. The air flows from the inlet through the pre-filter, followed by the ESP ionization zone and collector plates, then through the HEPA filter and activated carbon filter, and finally exits through the fan-driven outlet. This structured flow ensures progressive removal of contaminants at each stage, improving efficiency while minimizing pressure drop.

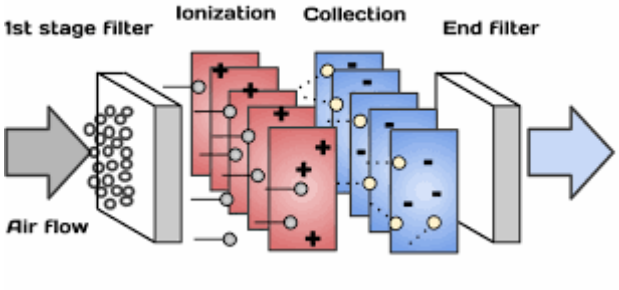

Fig.2.Methodology

Air flow is the rate at which air moves from point of elevated pressure to point of inferior pressure a purpose of the magnitude of driving pressure which is the distinction among the pressure at the commencement of the tube and the pressure at the last part of the tube. The airflow which is represented as two blue arrows pointing right with dust particles which are specified as green circles, passes between charger electrodes which are specified as blue vertical rods, at negative electrical potential ranging from a few kilovolts to tens of kilovolts. Particles are charged negatively, the blue circles and are subsequently attached to collector plates, the red square sheets, which is at affirmative electrical potential of a few to tens of kilovolts as depicted in fig.3.

ESP is an air filtering device that uses electrostatic charge for dust particles removal. ESP works by ionizing air through the application of high voltage on the electrodes. The dust particles are then charged by the ionized air and collected on the oppositely charged collecting plates. Since ESP removes dust and smoke from the gas, it can be used for a wide range of biomass materials such as wood, faeces, and poor-quality coal, which produce a lot of smoulder. Additionally, ESP has a collection efficiency, which is the ratio of the count of particles entering and leaving the filter, which is greater than 99 % as long as the appropriate design strategy is used, it is possible to design a versatile low-power ESP air cleaner.

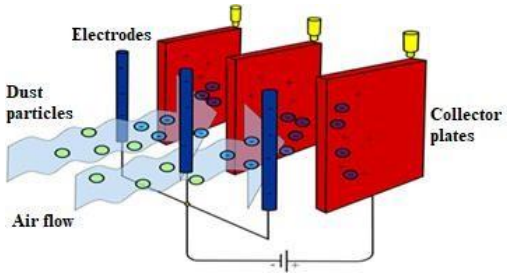

Fig 3. ESP - air flow as input parameter

The most important ESP concert indicators are the concentration of particulate matters (PM), opacity, secondary corona power, secondary voltage, which is the voltage on the electrodes, and derivative current, which is the current on the electrodes. The erstwhile ESP performance indicators are spark rate, principal current, principal voltage, bay gas temperature, gas flow rate, rapper, and number of fields in operation.

III. EXPRIMENTAL PROCEDURE

The operation of an air purifier can be described as a multi-stage process involving coordinated action between key components such as filters, an electrostatic precipitator (ESP), and a motor-driven fan. These components function collectively to remove airborne contaminants and deliver clean air to the surroundings. The purification process typically consists of three primary stages: pre-filtration, electrostatic precipitation, and high-efficiency particulate air (HEPA) filtration. In the first stage, the incoming air passes through a pre-filter, where larger particulate matter such as dust, lint, and hair is captured. This stage serves to reduce the load on subsequent filtration units and enhances overall system efficiency.

In the second stage, the partially cleaned air enters the electrostatic precipitator. Here, particles are electrically charged and subsequently attracted to oppositely charged collection plates, enabling the removal of fine particulates that are not effectively captured by mechanical filters. Following electrostatic precipitation, the air is directed through a HEPA filter, which is capable of trapping extremely fine particles, including microscopic dust and residual pollutants. This stage ensures a high level of purification by removing particles that remain suspended after the earlier processes.

Finally, the purified air is discharged into the environment with the assistance of a motorized fan, which maintains continuous airflow through the system. The experimental methodology involves evaluating the performance of the air filtration system under controlled operating conditions. The system is tested by allowing polluted air to pass through the purification stages while monitoring key parameters such as applied voltage, airflow rate, particle size distribution, and dust loading. The applied voltage for the ESP typically ranges between 5 kV and 30 kV, while the airflow rate is maintained around 1.5 to 2.0 m^3/s. Particle sizes considered in the study range from 0.1 µm to 10 µm, representing common airborne pollutants.

The experimental setup consists of a duct-based airflow system integrated with ESP electrodes and filtration units. A high-voltage DC supply is used to energize the corona wires, while a motor-driven fan maintains consistent airflow through the system. Measurements are taken at both the inlet and outlet to determine particle concentration, enabling the calculation of collection efficiency. Additional parameters such as current, voltage, and air velocity are also recorded to analyse system performance. The test parameters are specified in the table 1. The overall arrangement of the fabricated air purifier setup, illustrating these components and their integration, is shown in Fig. 4.

Table 1. ESP test parameters

Parameter	Value
ESP Efficiency (initial)	80%
ESP Efficiency (after loading)	70%
HEPA Efficiency	99.95%
Overall System Efficiency	89.25%
Drift Velocity	17.36 m/s

Fig.4. Fabricated air purifier set up

IV. RESULTS AND DISCUSSION

Drift velocity is calculated by diving the current I by n- free electron density for aluminium A- area of collector plate and e- electric charge. V $= I/nAe$ = V =0.03/ $(6*10^{16})$ *(.18) *$(1.6*10^{-19})$ = 17.36 m/s. The collection efficiency η = 1- $e^{(-VA/Q)}$ = 0.975 i.e. 97.5% where Q is the volumetric flow 1.97 m^3/sec.

A HEPA filter is typically considered as MERV 17 to 20, which is the highest group in MERV ratings. From the filter efficiency guide, it is observed that the standard efficiency of HEPA filter is 99.95%. The overall efficiency of 89.25% of the product is calculated by the average of collector and HEPA efficiency. The comparison of ESP filter with the conventional filter is depicted in table 2.

Table 2. Comparison of ESP with existing system

Feature	Conventional Filter	Proposed System
Pressure Drop	High	Low
Efficiency	Moderate	High
Maintenance	Frequent	Reduced
Portability	Limited	Yes

V. CONCLUSION

The electrostatic precipitator (ESP) developed in this study demonstrated a peak collection efficiency of approximately 80% during the initial phase of operation. However, as particulate accumulation on the collection surfaces increased, a gradual decline in efficiency was observed. Among the design parameters, the spacing between the collection plates was found to have a more pronounced effect on performance than the spacing between corona wires. For stable and safe operation, a minimum inter-plate distance of about 50 mm is recommended. Over time, the build-up of dust with a cumulative value around 2 kg/m, corresponding to nearly two hours of continuous operation led to a reduction in efficiency from 80% to about 70%. Interestingly, beyond this period, after approximately 120 minutes, an improvement in system performance was noted, which may be attributed to stabilization of particle deposition and electric field distribution within the ESP.

Overall, the proposed ESP system offers a cost-effective and practical solution, particularly suited for small and medium-scale industries relying on wood combustion. Its performance is adequate for reducing harmful emissions, including polycyclic aromatic hydrocarbons (PAHs), thereby contributing to improved air quality and environmental protection. An air purifier helps trap dust before it settles and can remove up to 99% of airborne bacteria, improving indoor air quality. Good health is very important for daily life, and air pollution controls systems help protect people from harmful pollutants. Most air cleaner standards test only new devices and do not consider by-products other than ozone. Electrostatic precipitators (ESPs) have lower pressure drop than mechanical filters while still removing particles effectively. The position of a portable air cleaner also affects how well it removes particles and protects people. Air pollution control can reduce environmental damage such as crop loss and water pollution and help prevent economic problems. When pollution is controlled, people stay healthier and can work more efficiently. Overall, air pollution control systems help maintain clean and safe air inside homes.

Abstract--: With the growing number of electrical appliances in modern homes, managing energy efficiently has become more important than ever. It is not only about reducing electricity bills but also about maintaining stability in the power grid.
This project introduces an Intelligent Home Energy System that combines IoT (Internet of Things) and Artificial Intelligence to monitor and predict energy consumption. The system uses an Arduino UNO along with sensors like ACS712 (current sensor) and DHT11 (temperature and humidity sensor) to collect real-time data such as voltage, current, and power factor.
A machine learning model (Random Forest Regressor) is used to analyse this data and predict future energy usage. It can also detect unusual consumption patterns, which may indicate faults or cyber threats.
The results show that by prioritizing essential appliances and providing real-time feedback through an IoT dashboard, energy waste can be significantly reduced.
Keywords: IoT, Smart Grid, Machine Learning, Arduino UNO, Energy Management System, Random Forest

I. Introduction

Traditional electricity meters only show the total energy consumed, which makes it difficult for users to understand which appliances are inefficient.

This system solves that problem by offering real-time monitoring through a centralized IoT platform. The Arduino UNO continuously measures voltage and current to calculate power usage and power factor.

An AI assistant then studies this data, learns user habits, and provides useful suggestions—like shifting heavy electricity usage to off-peak hours to save cost.

II. Literature Review

Several studies have contributed to the development of smart energy systems:

- Smart Meters & Business Intelligence (Raza et al., 2023):
  Smart meters play a key role in modern energy systems by using IoT to handle large amounts of data efficiently.
- IoT-Based Energy Management (Saleem et al., 2021): Smart systems allow two-way communication and remote control of appliances, making energy usage more flexible.
- Security in Smart Systems (Hseiki & El-Hajj, 2024): Protecting energy systems from cyber-attacks is essential. Technologies like LoRaWAN improve reliability.
- Data Integrity (Kumar, 2023): Cyber-attacks can disrupt energy data completely, highlighting the importance of anomaly detection.
- Power Line Communication (Sausen, 2021): PLC technology helps in remote monitoring and fault detection in urban power networks.

III. Existing System Analysis

Conventional systems often utilize standard Voltage Source Inverters (VSI) and boost converters.

- Capacitor Reliability: Standard EV inverters often use Aluminum Electrolytic Capacitors (Al-caps) which have shorter lifespans compared to Metallized Polypropylene Film (MPPF) capacitors.
- Efficiency Losses: High-voltage ratio boost converters operate with high duty cycles, leading to significant switching and magnetic losses.
- Hardware Con Capacitor Reliability: In many electric vehicle inverters, Aluminum Electrolytic Capacitors (Al-caps) are commonly used. While they are cost-effective, they tend to have a shorter lifespan compared to more durable options like Metallized Polypropylene Film (MPPF) capacitors.

- Efficiency Losses: Boost converters operating at high voltage ratios often require high duty cycles. This results in increased switching and magnetic losses, ultimately reducing overall efficiency.
- Hardware Constraints: To handle high power levels, these systems require large inductors. Unfortunately, these components are not only bulky and expensive but also prone to core losses, which further impacts performance.
- straints: Large inductors required for high power ratings are heavy, costly, and suffer from core losses.
-

IV. Proposed System Architecture

he proposed system goes beyond basic energy measurement and moves toward automated power flow management, making the entire process smarter and more efficient.

A. Priority-Based Load Management

The system intelligently identifies and classifies household appliances based on their importance:

1. Critical-Loads:
   These are essential devices such as refrigerators and security systems that must remain powered at all times without interruption.
2. Non-Priority-Loads:
   These devices are less critical and can be turned off or operated at reduced levels during peak hours to avoid high electricity costs.

B. Integration of AI and IoT

At the core of the system lies an intelligent layer powered by a Random Forest Regressor (RFR). This model is trained using historical data, including parameters like current, voltage, power factor, type of day (weekday or weekend), seasonal variations, temperature, and humidity.

By analyzing these factors, the system can accurately predict future energy consumption. Additionally, it is capable of identifying unusual patterns in the data, which may indicate potential issues such as faulty usage or even malicious energy data attacks.

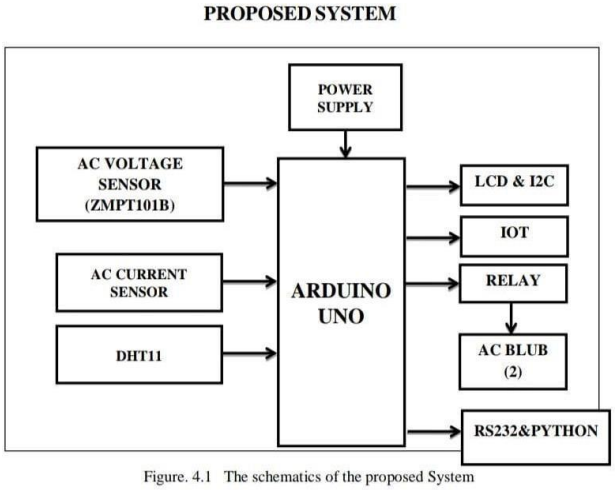

Figure. 4.1 The schematics of the proposed System

V. Hardware and Software Design

1) Hardware Components

 Arduino UNO – At the heart of the system is the Arduino UNO, powered by the ATmega328P microcontroller. It acts as the central hub, collecting and processing data from all connected sensors. To protect against accidental surges, it includes a resettable polyfuse that trips if the USB current exceeds 500mA.

 ACS712 Current Sensor – This Hall Effect-based sensor measures current flow up to 30A. With an internal resistance of just 1.2 mΩ, it ensures accurate readings while keeping power losses to a minimum.

 DHT11 Sensor – Responsible for monitoring environmental conditions, the DHT11 provides reliable measurements of relative humidity (20–90% RH) and temperature (0–50°C).

 16x2 LCD Display – Using the HD4478 controller with an I2C interface, this display presents real-time power and environmental metrics in a clear, easy-to-read format directly on the device.

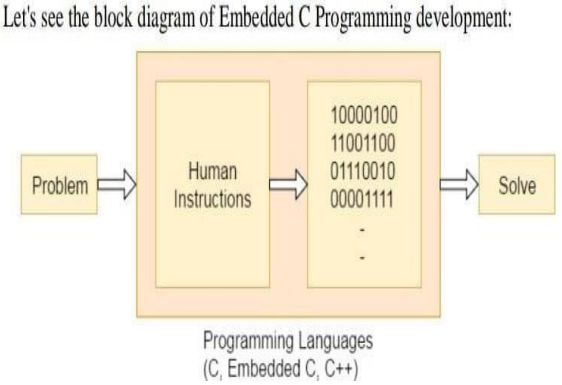
2) Software Implementation

 Embedded C on Arduino: Acts as the reliable “hands-on” controller, ensuring peripherals respond quickly and consistently. Think of it as the steady pilot keeping the hardware in check.

 Python Backend: Handles the heavy lifting—running AI computations and managing IoT communication. It talks to the Arduino over a serial link at 9600 baud, making sure data flows smoothly between brain and body.

 IoT Infrastructure: Provides the connective tissue that makes everything “plug and play.” Devices can be discovered and controlled remotely across existing networks, so integration feels seamless rather than complicated.

-



Working Principle

The Intelligent Home Energy System works like a smart companion for your house. With its built-in AI Energy Assistant, it’s always keeping an eye on how your appliances use electricity. Instead of just measuring, it actively analyzes patterns—spotting when devices are wasting energy or running inefficiently. Then, it steps in to optimize usage, making sure power is consumed wisely. The result? Lower

bills, less waste, and a home that feels effortlessly efficient without you having to constantly monitor it.

The working process begins with the sensing layer, where voltage and current sensors are installed to measure electrical parameters of the connected loads. These sensors continuously capture real-time data related to voltage, current, and power consumption of household devices.

The collected data is transmitted to a microcontroller, which acts as the central processing unit of the system. The microcontroller processes the sensor inputs and calculates the instantaneous power consumption and total energy usage of each appliance. This information is then transmitted to a cloud platform through a wireless communication module such as Wi-Fi or IoT gateway.

The cloud server stores the received data in a database and provides a real-time monitoring interface through a web dashboard or mobile application. Users can view their energy usage statistics, historical consumption data, and appliance-level energy distribution. This transparency helps users understand their electricity usage patterns and identify devices that consume excessive energy.

Artificial Intelligence algorithms analyze the stored data to detect usage patterns and predict future energy demand. Machine learning models can forecast peak usage periods and recommend optimal operating schedules for appliances. Based on these predictions, the system can automatically control appliances through relay modules by turning off non-essential devices during peak demand periods.

The system also provides alerts and energy saving suggestions to users when abnormal energy consumption is detected. By blending IoT sensors, cloud intelligence, and AI predictions, the system becomes like a smart energy coach for your home. The sensors keep track of how appliances are using electricity, the cloud processes that data in real time, and the AI forecasts future needs. Together, they make sure energy is used efficiently, cut down on unnecessary waste, and help your household run in a more sustainable way—saving money while being kinder to the planet.

VI. Results and Discussion

This system isn't just a passive observer—it's an active partner in managing household energy. By continuously calculating the Power Factor (PF), it highlights appliances that are running inefficiently. A PF far from 1.0 is like a red flag, signaling to homeowners which devices are quietly wasting energy.

Beyond monitoring, the AI-driven predictive model acts almost like a financial advisor. It forecasts upcoming electricity bills, giving families the chance to adjust usage before the billing cycle ends. Instead of being surprised by high costs, users can plan ahead and make smarter choices.

The IoT dashboard adds another layer of convenience. Even when away from home, users can check in on their appliances, switch off devices remotely, and eliminate "phantom loads"—those sneaky electronics that keep drawing power even when idle. Together, these features transform energy management into something proactive, efficient, and user-friendly

VII. Conclusion and Future Scope

The Intelligent Home Energy System demonstrates how AI and IoT can work hand-in-hand to create homes that are smarter, greener, and more cost-effective. It doesn't just monitor—it learns, predicts, and guides households toward sustainable living.

Looking forward, the system could evolve with exciting enhancements:

- Renewable Integration: Directly managing solar panels to reduce grid reliance and maximize clean energy use.
- Voice Control: Seamless integration with assistants like Alexa or Google Assistant, making energy management as simple as speaking a command.
- Blockchain Energy Trading: Enabling secure peer-to-peer energy sharing, where homes trade excess power with neighbors, building a community-driven marketplace.

These upgrades point toward a future where homes aren't just consumers of energy—they become intelligent, active participants in a sustainable ecosystem.

Abstract—People are using banking more and more. A lot of users still have a hard time understanding investment options. This is because they do not know much about money and they may not speak the language well.

The Multilingual AI Financial Advisor is a system that helps users pick the investment plans. It talks to users in their language. Looks at their financial situation.

Users can select a bank the language they want to use and some financial information. They can tell the Multilingual AI Financial Advisor how old they are, how money they want to invest and what is in their bank account.

The Multilingual AI Financial Advisor uses computers to look at all the investment options that the bank has. Then it suggests the way to invest money based on what the user told the Multilingual AI Financial Advisor. The Multilingual AI Financial Advisor also explains why it made that suggestion.

The Multilingual AI Financial Advisor looks at how happy the users. Then it. Sets up a meeting with the people who work at the bank or sends automated messages about investments.

When we tried out the Multilingual AI Financial Advisor we found that the system gives advice, about money. It makes it easier for people to use the Multilingual AI Financial Advisor because it can talk to them in languages. The Multilingual AI Financial Advisor helps users trust it more because it explains what it is doing with the intelligence.

I. INTRODUCTION

Investment planning is super important for stability and growing your wealth. Many people find it tough to pick the financial products. They don't know much about finance and banking info can be confusing. There are language barriers. Traditional financial advisory services need experts, which can be costly and hard to get for people. Thanks to Artificial Intelligence and Natural Language Processing we can now create chat systems that help users make decisions. Multilingual AI systems are really helpful because they let users talk in their language and get financial advice that easy to understand. Some recent studies on chatbot have found that pre-trained language models and translation systems can help people communicate across languages. These systems are already being used in areas like healthcare, education and customer service, where users benefit from automated help. This paper is about a Multilingual AI Financial Advisor. It is designed to look at a user profile and suggest investment options from certain banks. The Multilingual AI Financial Advisor system gets investment data processes what the user says gives recommendations and explains why it makes each decision. The system uses Artificial Intelligence and Natural Language Processing to analyze and provide recommendations. This Multilingual AI Financial Advisor can help users make investment decisions. It provides users with explanations, for its suggestions. The goal of the Multilingual AI Financial Advisor is to make financial planning easier and more accessible. The main things that this research does include: It creates an advisory chatbot that people who speak different languages can use. It automatically finds out what investment options are available from the bank. It uses intelligence to suggest investments to people. The financial advisory chatbot can explain why it makes decisions. It works with banking services so people can schedule appointments or start investing without having to do much themselves. The research is, about an advisory chatbot and it does these things. Financial planning is an essential tool for individuals to attain financial stability and create wealth over a period. Nevertheless, a majority of the population is not aware of financial instruments such as fixed deposits, mutual funds, pension plans, and bonds. The understanding of such financial opportunities requires knowledge of banking terminology and investing strategies, which many users do not possess.

II. PROBLEM STATEMENT

Another key challenge associated with such financial advisory services is the language barrier. Most financial services and banking websites only offer services in English. Hence, people who are more comfortable reading and understanding regional languages face difficulties in understanding such financial opportunities and advisory services.

Financial advisory services are also very expensive and inaccessible to many people. Financial advisors are only available for high-value customers and require a consultation fee. Hence, many people either refrain from investing in such financial opportunities or make poor financial decisions due to a lack of proper guidance.

With the rapid advancement of Artificial Intelligence (AI) and Natural Language Processing (NLP), it is now possible to

develop intelligent systems that can provide automated financial guidance. Nevertheless, the need for a system that can communicate in multiple languages, analyze the financial data of the users, and provide investment recommendations to the users in a simple manner is still felt.

Therefore, the need for a multilingual AI financial advisor is proposed as a project that can bridge the gap between complex financial systems and users by providing financial advice to the users.

III. Objectives

The main objective of the project is to create a smart financial advisory system that can aid users in making informed decisions through a multilingual conversational interface.

The specific objectives of the project are as follows:

To create a smart financial chatbot using the AI chatbot concept, which can converse with users in different languages.

To obtain user financial information, including age, investment amount, bank balance, etc.

To obtain investment options from banking institutions using web scraping techniques.

To create a recommendation system that can analyze user profiles and recommend investment plans accordingly.

To incorporate XAI techniques so that the system can explain the reasoning behind the recommendation system.

To increase the level of financial inclusion for users by simplifying complex financial information for users.

To create a system for users to schedule appointments with banking institutions or for sending messages for investments.

The main objective of the project is to create a smart financial advisory system that can aid users with different language backgrounds and varying levels of financial knowledge.

IV. Background

Conversational Artificial Intelligence has changed a lot from the systems like ELIZA to the new intelligent assistants that use deep learning. The old chatbots used to give answers that were already decided. They could not understand the situation or work with different languages. Now because of the developments in neural networks and models like BERT and GPT systems can understand complicated language patterns and give answers that sound natural. This means that chatbots can help people who speak languages and give them personalized suggestions. A system that can have conversations in languages has several parts: Natural Language Processing that helps the system talk to the user. Machine translation that helps people who speak different languages communicate. Knowledge graphs that give information about the situation. Machine learning models that help the system give smart answers. Studies have shown that multilingual conversational Artificial Intelligence systems make things more accessible by letting users talk in their own languages. This is very important in services, where it is crucial to understand investment products correctly. People are also paying attention to combining Artificial Intelligence with systems that help with decisions. Artificial Intelligence based financial advisors can look at investment portfolios figure out how risk a user is willing to take and suggest financial products that are right for the user based on their profile. Multilingual conversational Artificial Intelligence systems, like these are very useful because they can support languages and give personalized recommendations, which is what multilingual conversational Artificial Intelligence systems are designed to do.

V. LITERATURE REVIEW

The creation of AI-powered conversational systems in various fields has been the subject of numerous studies. Görtz et al. showed how AI chatbots can enhance information accessibility by creating a healthcare chatbot intended to inform patients about prostate cancer. Zhou et al. proposed an AI chatbot that used natural language interaction to raise awareness of Covid-19 vaccination. Verma et al. combined knowledge graphs and conversational agents to offer intelligent academic support in educational settings. In a similar vein, Patel et al. created a chatbot that is integrated with learning management systems to facilitate individualised student counselling. Research on multilingual chatbots has also advanced dramatically. During a pandemic, Yang et al. created a multilingual natural language processing system that can handle queries in several languages.

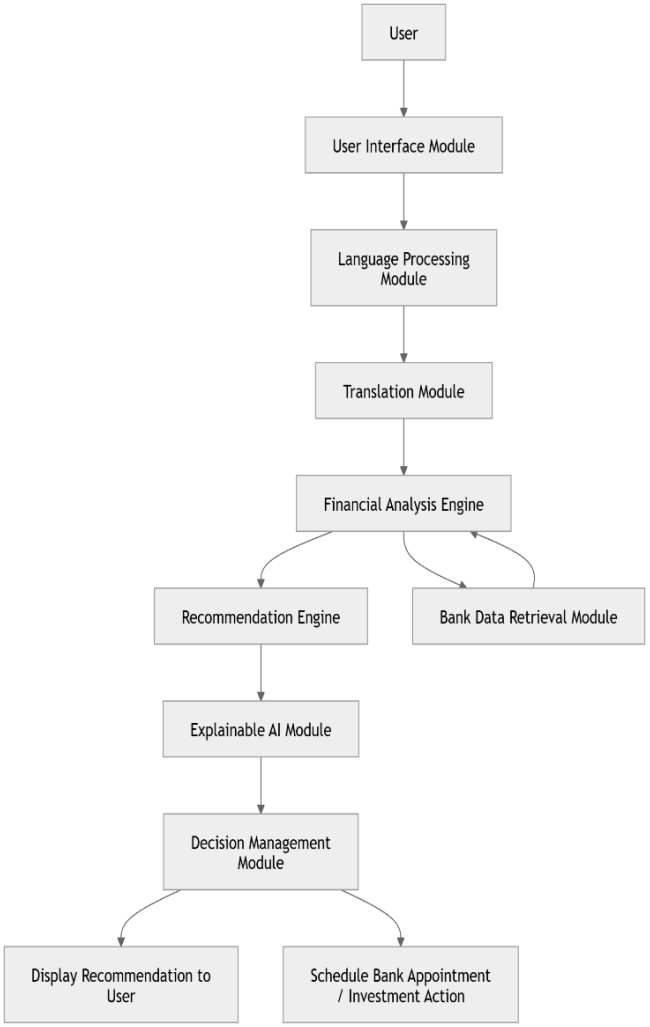
Numerous studies have been conducted on the development of AI-powered conversational systems in various fields. By developing a healthcare chatbot designed to educate patients about prostate cancer, Görtz et al. demonstrated how AI chatbots can improve information accessibility. In order to increase awareness of the Covid-19 vaccination, Zhou et al. proposed an AI chatbot that used natural language interaction. Knowledge graphs and conversational agents were combined by Verma et al. to provide intelligent academic support in learning environments. Similarly, in order to enable customised student counselling, Patel et al. developed a chatbot that is integrated with learning management systems. Additionally, multilingual chatbot research has made significant strides. Yang et al. developed a multilingual natural language processing system that can respond to queries in multiple languages during a pandemic.

VI. Methodology and Implementation

A. System Architecture:

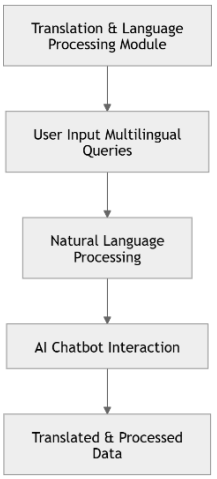
A strong, modular architecture built to manage the challenges of real-time financial data and multilingual user interaction forms the basis of the suggested system. Instead of depending on a single, monolithic process, the system is made up of interconnected parts that cooperate to convert

unprocessed user input into clear, actionable investment advice.



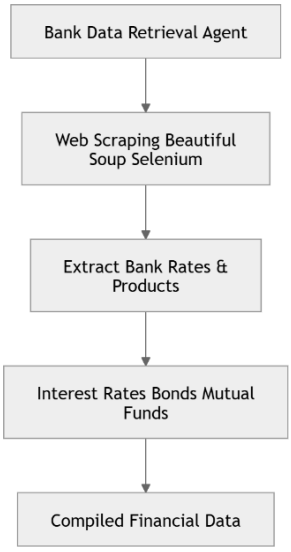
B. Translation and Language Processing Module

The creation of AI-powered conversational systems in various fields has been the subject of numerous studies.Görtz et al. showed how AI chatbots can enhance information accessibility by creating a healthcare chatbot intended to inform patients about prostate cancer. Zhou et al. proposed an AI chatbot that used natural language interaction to raise awareness of COVID-19 vaccination.Verma et al. combined knowledge graphs and conversational agents to offer intelligent academic support in educational settings. In a similar vein, Patel et al. created a chatbot that is integrated with learning management systems to facilitate individualized student counseling.



C. Bank Data Retrieval Agent

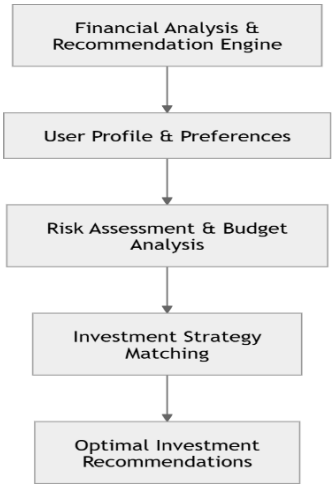
The Retrieval Agent, which functions as an automated researcher, is essential to the system's capacity to offer up-to-date guidance. The agent uses web scraping tools such as Beautiful Soup and Selenium to navigate bank websites and extract the latest investment products. This comprises: Compiling interest rates and maturity terms for bonds and fixed deposits. Pension plans and mutual funds: obtaining eligibility requirements and performance information.



D. Financial Analysis and Recommendation Engine

The Analysis Engine, which compares the user's profile to the retrieved bank data, is the central component of the system. This engine assesses a number of crucial factors to guarantee that the guidance is customized: Demographic Alignment: Evaluating how a user's age affects their ability to take risks. Capital Constraints: Evaluating the bank balance and investment budget in relation to the minimum entry requirements for different funds. Matching short-term or long-term financial instruments with the investment duration (time horizon) is known as temporal planning. Portfolio Strategy: Examining the specifics of the current portfolio to recommend ways to diversify.

The best investment plan is then chosen by the Recommendation Engine using a combination of machine learning models—built with TensorFlow and Scikit-learn—and rule-based logic.



E. Decision Management and Explainable AI (XAI)

Through the Explainable AI Module, the system offers a "why" in addition to a result in order to build user trust. This module provides a clear justification for the selected path by dissecting the reasoning behind the recommendation engine. Ultimately, the Decision Management Module assesses user satisfaction and enables the subsequent logical action, such as setting up a formal meeting with bank staff or automatically starting the investment communication.

VII. Specifics of Implementation

Python and contemporary AI libraries are used in the system's implementation.

Python is the programming language.

Technologies Employed

The web interface is called Streamlit.

- Web scraping bank data using BeautifulSoup and Selenium
- Google Translate API: Support for multiple languages
- Scikit-learn and TensorFlow: Recommendation models
- NumPy and Pandas: Data processing
- Matplotlib: Workflow for Visualization

The user chooses their preferred bank and language. The system gathers the user's financial data. Web scraping is used to obtain bank investment options. The user profile is assessed by the financial analysis engine. An appropriate investment plan is chosen by the recommendation engine. The Explainable AI module offers logic. The level of user satisfaction is assessed. The system starts an investment or makes an appointment

VIII. Use Case Scenario

In order to clearly understand the functionality of the proposed system, a user scenario for the proposed system is discussed below:

A user interested in seeking financial advice opens the Multilingual AI Financial Advisor application using a web interface. The first prompt from the proposed system is for the user to select their preferred language from a set of languages like English, Tamil, Hindi, etc.

Once the user selects their preferred language, they are then prompted to enter some basic financial details like:

Age

Monthly income

Amount available for investment

Bank balance

Investment Duration or Financial Goal

Once the user enters the required information, the system processes the details and retrieves the relevant investment products from the bank database through the Bank Data Retrieval Agent.

The Financial Analysis Engine analyzes the user profile and compares the various investment options according to the level of risk, expected returns, and investment duration.

The system, through the Recommendation Engine, provides a recommendation for the user's investment. For instance, the system may recommend a mutual fund scheme for a user who is young and willing to take more investment risks. On the contrary, the system may recommend a fixed deposit or a pension scheme for a user who wants to invest safely.

Finally, the system, through the Explainable AI module, provides a clear explanation for the recommendation. For instance, the system may explain the recommendation by stating that the recommended plan is suitable for the user due to the user's age, investment amount, and financial goals.

Subsequently, the system requests the user whether he or she is satisfied with the recommendation. Once the user confirms satisfaction with the recommendation, the system can either:

Schedule a meeting with a bank representative, or

Provide more information on how to begin the investment process.

IX. Results and Discussion

A. *Performance Metrics*

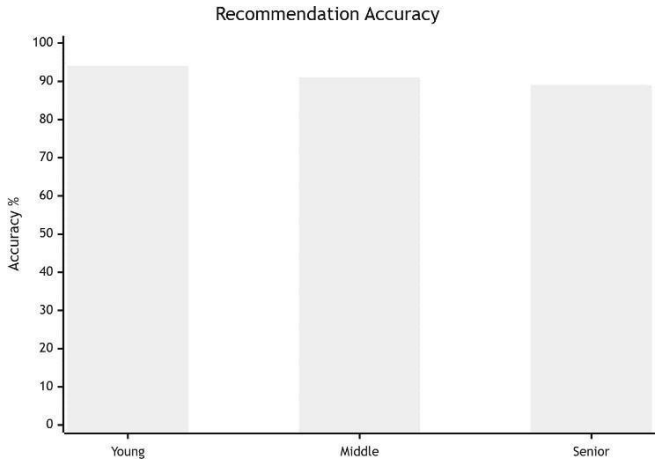
The following metrics were used to measure the performance of the system:
Recommendation Accuracy
Whether the recommended investment plan is consistent with the recommendations of financial experts.
Response Time
The time taken for the system to generate the response.
User Satisfaction Score
Feedback from the users on a scale of 1 to 5.
Performance Metrics:

Recommendation Accuracy	92%
Average Response Time	2.3 seconds
User Satisfaction	4.3 / 5

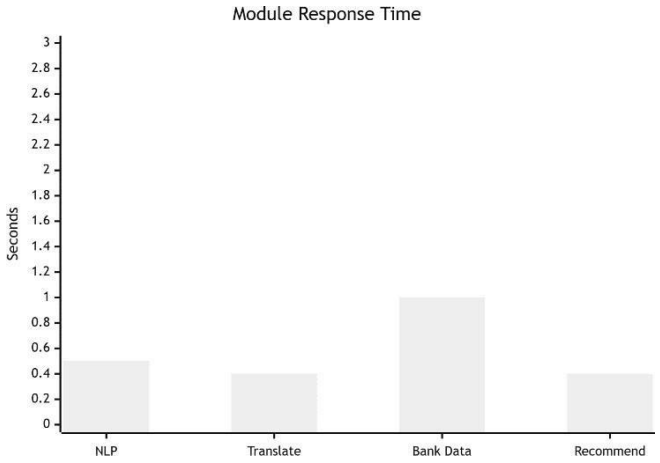
B. *Graphical Analysis*

Graphical analysis is a way to measure the performance of the system for various investment scenarios.
Graphs:

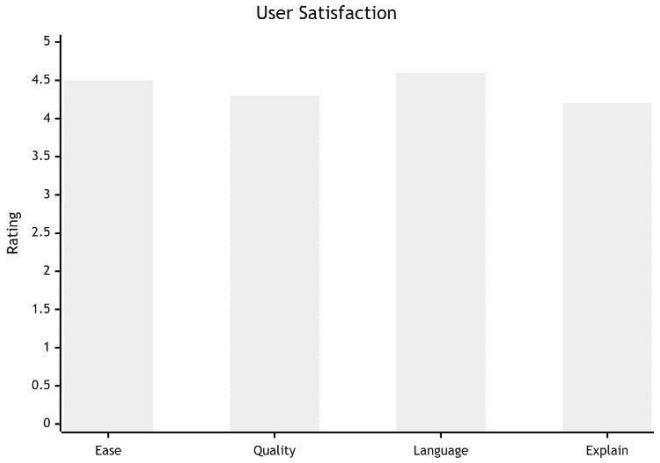
1. Recommendation Accuracy Graph



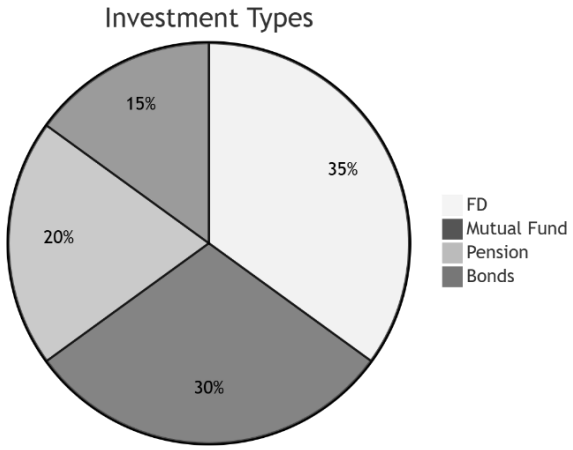
2. System Response Time Graph



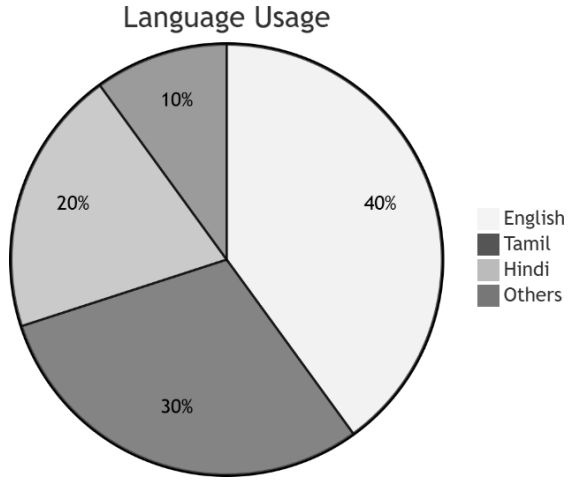
3. User Satisfaction Graph



4. Investment Recommendation



5. Distribution Language Usage Graph



C. Interpretation and Insights

From the experimental results, the following conclusions were drawn:

Users prefer to communicate in their mother tongue when it comes to discussing financial decisions.

Explainable AI helps users trust the automated financial advisor.

The system performs well when there is sufficient data available for investment in banks.

Multilingual support has a significant impact on the accessibility of the financial

The current study offers a novel system for a Multilingual AI Financial Advisor that can assist users in making the best decisions regarding investment plans based on their financial analysis.

The results of the experiment have confirmed the efficiency of the proposed system regarding user experience and system accuracy. The addition of the explainable AI reasoning module also increases the trustworthiness of the financial advice provided

X. Advantages of the Proposed System

The proposed Multilingual AI Financial Advisor system has several advantages over the traditional methods of providing financial advice to the users.

1. Multilingual Communication
   The users can communicate in their preferred language using this system.
2. Personalized Financial Recommendations
   The users can get personalized financial recommendations from this system.
3. Cost-Effective Solution
   The users don't have to pay consultation charges while using this system.
4. Improved Financial Accessibility
   The users with different educational backgrounds can understand financial terms using this system.
5. Explainable AI Support
   The users can understand the reasoning behind each recommendation made by this system.
6. Real-Time Data Retrieval
   The users can get real-time data using web scraping techniques from banking websites.
7. Time Efficiency
   The users can get instant replies and recommendations from this system within a matter of seconds.

XI. Limitations of the Proposed System

As discussed in the above points, there are various advantages in the proposed system. However, there are some limitations in this system.

1. Dependence on Internet Connectivity
   As discussed in the above points, this system is based on internet data retrieval. So, this system must have internet connectivity for proper operation.
2. Limited Data Sources
   This system is based on financial data. So, this system will not provide accurate results if there is no sufficient financial data from bank websites.
3. Translation Accuracy Issues
   In this system, sometimes machine translation tools might not provide accurate results.
4. Limited Financial Scope
   This system is based on some specific banking investment products. However, this system might not cover other financial scopes such as stock market trading or cryptocurrency.
5. Privacy and Security Concerns
   As this system is based on user financial information, proper security measures must be implemented for this system.
6. Dependence on User Input Accuracy
   This system might not provide accurate results if users input incorrect financial information.

XII. FUTURE WORK

The Multilingual AI Financial Advisor system is really good at giving people personalized recommendations..

There are some things that can be done to make it even better.

One big thing that can be added to the Multilingual AI Financial Advisor system is voice-based interaction. Now people have to type to talk to the system. If we add speech recognition and speech synthesis people can just talk to the system. This will be great for people who're not very good at typing.

Another big thing that can be added to the Multilingual AI Financial Advisor system is real-time banking APIs. The system currently uses web scraping to get information from bank websites.

The Multilingual AI Financial Advisor system can also be made to work with languages. Now it only works with a few languages.

We can also make the Multilingual AI Financial Advisor system better at predicting what will happen with finances. We can use machine learning and deep learning algorithms to look at what happened in the past and what people are doing now. This will help the Multilingual AI Financial Advisor system give investment advice.

The Multilingual AI Financial Advisor system can also be used to help people manage their investments. It can track what people are investing in. Give them advice on what to do next.

It would be great if the Multilingual AI Financial Advisor system could be used on devices. We could make an app that lets people get financial advice anywhere and at any time.

We also need to make sure the Multilingual AI Financial Advisor system is safe and secure. We can use encryption and strong authentication to keep peoples information safe. We could even use blockchain technology to make sure transactions are secure.

The Multilingual AI Financial Advisor system will be great, for people who want to get financial advice. The future of the Multilingual AI Financial Advisor system is looking good.

XIII. Conclusions

The proposed system is an important step towards the development of an intelligent financial assistant for digital banking services that can serve a wide range of users. The current study offers a novel system for a Multilingual AI Financial Advisor that can assist users in making the best decisions regarding investment plans based on their financial analysis.

The results of the experiment have confirmed the efficiency of the proposed system regarding user experience and system accuracy. The addition of the explainable AI reasoning module also increases the trustworthiness of the financial advice provided.

The proposed system is an important step towards the development of an intelligent financial assistant for digital banking services that can serve a wide range of users.

Abstract*— Hazardous and disaster-prone environments can be found in mining areas, industrial zones, fire-affected buildings, and other structurally unsound areas. While keeping an eye on and saving people, these environments present significant risks. Because of the complex exposure to toxic gases, high temperatures, and unstable structures with poor visibility, manual inspection in these areas becomes dangerous. In the end, these elements will postpone rescues and raise the risk of harm or death. The paper proposes an IoT-based autonomous robotic system for hazard monitoring and disaster response based on this gap. In order to gather sensor data, analyze it in real time, and send it via Wi-Fi to a cloud-based IoT platform, an ESP32 microcontroller is integrated into the core processing unit. If hazardous levels are detected in the surroundings, the robot can identify an obstacle, halt, and sound an alarm. Adding an ESP32 camera allows rescue teams to remotely monitor the impacted area via live video streaming. Real-time monitoring, communication stability, gas detection speed, and obstacle detection capability are all tested on-site. In order to make it much safer to react and much faster, this paper suggests a system that makes it possible for humans to be present in such dangerous situations. This solution will provide a scalable and economical solution for disaster management, industrial safety monitoring, and emergency response use because it was developed at a moderate cost.

Keywords--Internet of Things, Autonomous Robot, Environmental Sensors, ESP32 Microcontroller, Hazard Monitoring, Disaster Response, and Real-Time Monitoring

I. INTRODUCTION

Hazardous conditions that endanger human life are frequently created by natural disasters, industrial mishaps, gas leaks, fires, and building collapses. Toxic gases, high temperatures, unstable structures, and poor visibility make manual inspection and monitoring extremely dangerous in these circumstances. In order to evaluate the damage and spot potential threats, rescue personnel and industrial workers may need to enter these dangerous areas, which puts their lives in danger. It is now feasible to create intelligent systems that can carry out monitoring tasks automatically thanks to advancements in robotics, embedded systems, and Internet of Things (IoT) technology. IoT technology enables remote data collection, real-time monitoring, and centralized system management. This lessens the necessity for people to go directly into dangerous areas.

An IoT-based autonomous robotic system intended to monitor environmental conditions in disaster-prone areas is presented in this project. The system makes use of an ESP32 microcontroller that is linked to various sensors, including MEMS, temperature, gas, and ultrasonic sensors. For real-time monitoring and analysis, these sensors gather environmental data and transmit it to an Internet of Things platform. Additionally, live video streaming is provided by an camera module, allowing operators to view dangerous areas from a safe distance.

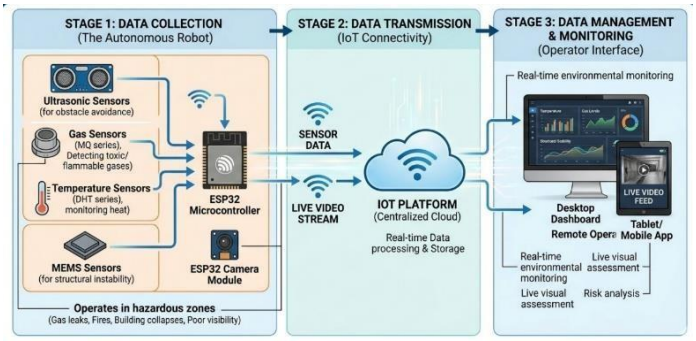

Fig.1 .Iot Enabled Autonomous Robot

By limiting human exposure to hazardous situations, the suggested system increases safety. Additionally, it facilitates continuous monitoring and quicker response, which makes it beneficial for industrial safety and disaster management applications.

II. PROPOSED SYSTEM METHODOLOGY

The proposed system is an autonomous robotic platform based on the Internet of Things (IoT) that can keep an eye on dangerous places and help with disaster response efforts. The robot has a number of sensors that can pick up on different kinds of dangers in the environment. An ultrasonic sensor helps the robot find things in its way, and a gas sensor finds dangerous gases like carbon monoxide and methane. A temperature sensor keeps an eye on high temperatures, and a MEMS sensor helps find vibrations and possible structural problems.

The main processing unit of the system is an ESP32 microcontroller. It gets data from all the sensors that are connected to it, processes the data in real time, and makes decisions on its own based on safety limits that have already been set. The robot stops right away when the ultrasonic sensor sees something close by to avoid crashing into it. If the gas concentration or temperature goes above safe levels, the system also sends warning alerts to an IoT cloud platform over Wi-Fi.

An ESP32 camera module also lets you stream live video, which lets people who are far away see the affected area and get a better idea of what's going on. The system reduces the need for people to go into dangerous places by combining sensing, communication, and autonomous control. It also makes sure that environmental monitoring is always happening and is reliable.

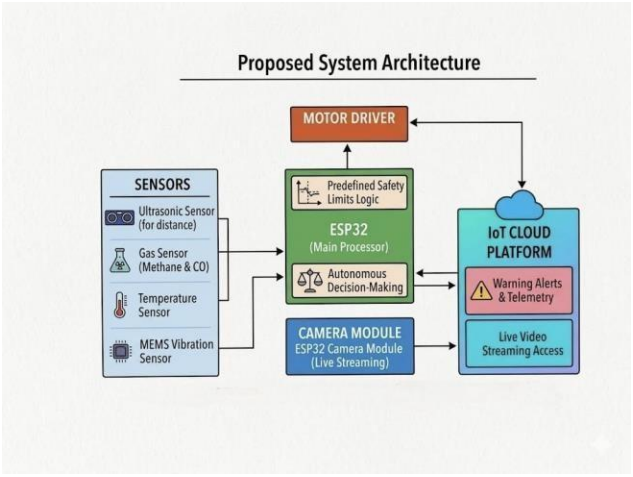

Fig.2 Block Diagram of Proposed System

III. System Architecture Design and Simulation

The suggested IoT-enabled autonomous robot is built with a modular and layered structure that makes it reliable, scalable, and able to monitor hazards in real time. There are three main layers in the system: the sensing layer, the processing and control layer, and the communication and monitoring layer. Each layer has a job to do, and together they make it possible for robots to work on their own and be watched from afar.

There are different environmental sensors on the robotic platform that make up the sensing layer. An ultrasonic sensor is on the front of the robot to find things that are in a certain distance. It sends out ultrasonic waves and measures how long it takes for the reflected signal to come back. This helps figure out how far away things are. An MQ-series gas sensor is an example of a gas sensor that can find harmful gases. It measures gas concentration in parts per million (ppm) and sends out an analog signal. A temperature sensor keeps an eye on the temperature around it, which is especially important in places where there has been a fire. The robot's chassis also has a MEMS sensor module with an accelerometer and gyroscope attached to it.

The ESP32 microcontroller is the main controller for the system, and the processing and control layer is built around it. The ESP32 is the best choice because it has a lot of processing power, built-in Wi-Fi, low power usage, and can handle both analog and digital input pins. The GPIO pins on the ESP32 connect the sensors to the board. The ultrasonic sensor's trigger and echo pins are connected to digital pins, while the gas and temperature sensors use either analog or digital inputs. The I2C communication protocol lets the MEMS sensor talk to the controller. The ESP32 reads the sensor data all the time and uses built-in C programs to process it.

The measured values are checked against safety limits that have already been set. The L298N motor driver module stops the robot's motors when the ultrasonic sensor sees something within a certain distance to avoid a crash. In the same way, if the temperature or gas concentration goes above safe levels, warning alerts are sent to the IoT cloud platform. The motor driver connects the microcontroller's low-power control signals to the higher-power DC motors. This lets the robot move forward, backward, or stop when it needs to.

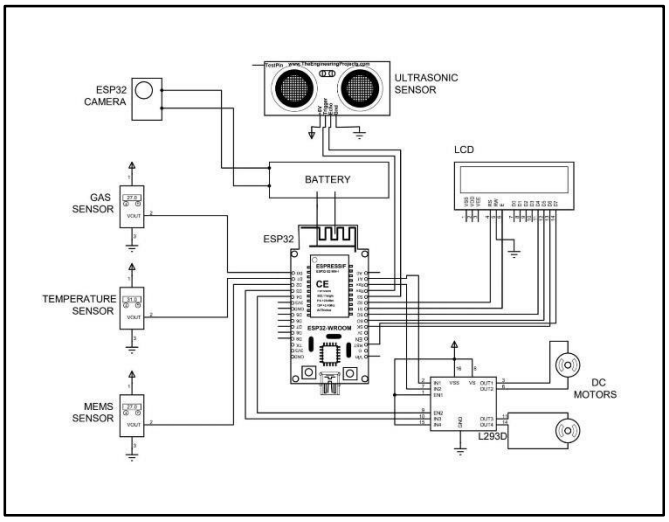

Fig.3 circuit Diagram of Iot Enabled Autonomous Robot

The communication and monitoring layer lets you access system data from a distance. The robot can connect to an IoT cloud platform like ThingSpeak or Blynk through the ESP32's built-in Wi-Fi module. The cloud gets sensor readings on a regular basis. These readings can then be shown on dashboards and charts. An ESP32 camera module is also built into the system so that it can stream live video. This lets people who are far away see dangerous places in real time. This layer lets you get to important data and visual information from a safe place, which means fewer people need to be in dangerous places.

A method simulation was used to confirm the system design and control logic prior to constructing the actual hardware prototype. Validating sensor interfacing, control algorithms, obstacle detection logic, hazard threshold conditions, and data transmission to the cloud were the main goals of the simulation. The Arduino IDE was used to create the embedded program, and the serial monitor was used to provide simulated sensor values so that the system's behavior under various circumstances could be observed.

To make sure the robot stops when the predetermined limit is reached, virtual obstacle detection tests were carried out during the simulation stage by providing various distance values. To confirm that the system produces alerts when hazardous gas levels are detected, gas sensor readings were also simulated. In order to verify that notifications are sent to the cloud platform correctly, temperature threshold tests were carried out. To assess the dependability of the wireless connection, communication delay during data transmission was tracked.

The results of the simulation showed that the control algorithm responds correctly to different sensor inputs and performs real-time decision-making effectively. Before putting the complete hardware prototype into use, this testing phase helped find possible problems early on, lowering hardware errors and enhancing system reliability.

IV. System Prototype Development and Testing

All necessary hardware components were integrated onto a mobile robotic chassis intended to function in hazardous and uneven environments to create the system prototype. DC motors power the robot's two-wheel differential drive system. The robot's direction and movement are managed by an L298N motor driver module, which controls these motors. The ESP32 microcontroller, sensors, and motor driver are powered by a rechargeable battery pack. In order to preserve a small layout and well-organized wiring, the ESP32 serves as the primary control unit and is firmly fixed on the chassis alongside the sensor modules.

Every piece of hardware was meticulously attached to the ESP32 according to its communication interface during the development phase. To enable efficient obstacle detection, the robot's front was equipped with an ultrasonic sensor. In order to manage the trigger and echo signals needed for distance measurement, it was linked to the digital GPIO pins of the ESP32. The MQ series gas sensor was connected to an analog input pin for continuous gas concentration monitoring, and it was positioned in an open area of the chassis to allow for appropriate air exposure. In order to measure ambient environmental conditions more precisely, the temperature sensor was placed externally.

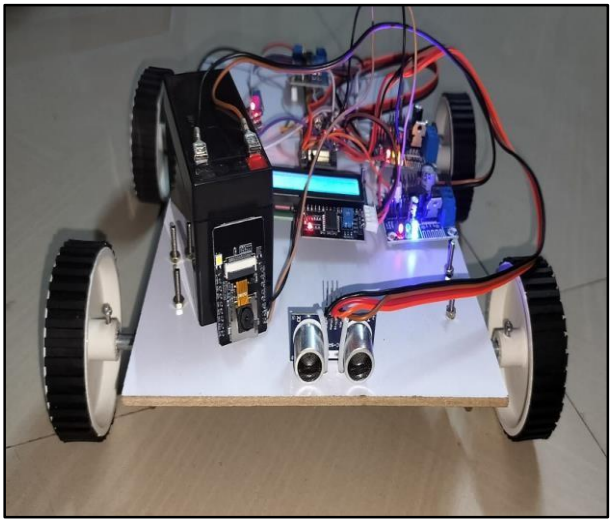

Fig.4 Hardware View

To identify vibrations, tilting, or abrupt movements that might point to structural instability, a MEMS sensor module, was securely fastened to the robot chassis. This sensor uses the I2C protocol to communicate with the ESP32. To provide a clear live video view of the surroundings, an ESP32 camera module was also installed on the robot at a slightly elevated position. To avoid short circuits and guarantee dependable operation, every electronic connection was thoughtfully placed and insulated.

Sensor initialization, data collection, threshold comparison, motor control, Wi-Fi connectivity, and IoT data transmission are just a few of the functional modules that make up the system's software, which was created using Embedded C programming in the Arduino IDE. For variables like gas concentration, temperature, obstacle distance, and vibration intensity, specific safety threshold values were established. The control logic was created so that the system instantly takes the necessary action whenever a parameter surpasses its safe limit. These include sending the sensor data to the IoT cloud platform, stopping the robot, and producing warning alerts.

The developed system was tested in several phases to confirm its performance and dependability. Initially, individual components were subjected to unit testing to verify their correct functioning. To confirm accuracy, the ultrasonic sensor was tested by measuring distances at different ranges. To test the gas sensor's sensitivity and reaction time, it was exposed to regulated gas sources. To guarantee measurement accuracy, temperature sensor readings were compared with those from standard thermometers. To verify that the MEMS sensor accurately identified motion and instability, the robot chassis was manually tilted and vibrated. Wi-Fi testing was also done on the camera module to assess transmission latency and video quality.

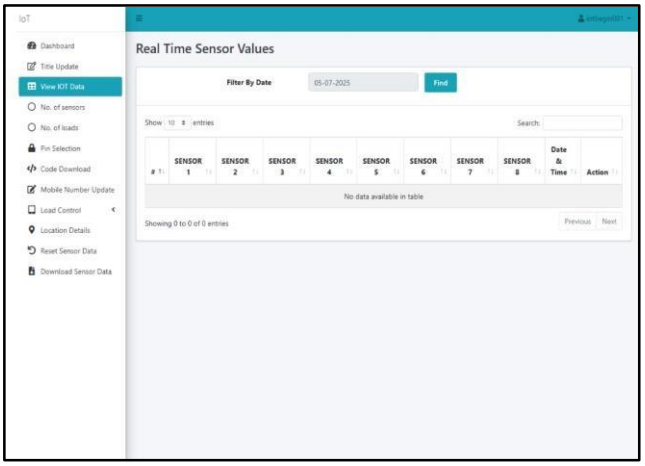

Fig.5 IOT Display

Integration testing was carried out to make sure that every component functioned properly following the completion of successful unit testing. The robot was used in a controlled setting that mimicked dangerous circumstances. In order to test sensor responses, temperature sources were added, obstacles were positioned along the robot's path, and controlled gas exposure was employed. System response time, data transmission latency, and alert generation were all closely observed during this phase. Additionally, the IoT dashboard was monitored to verify that notifications were consistently sent and that sensor data was updated in real time.

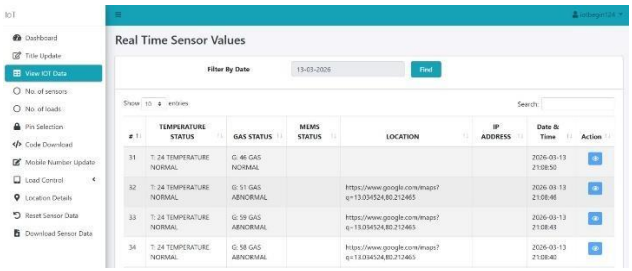

Fig.6 IOT Display

Lastly, field-level testing was conducted to assess the robot's overall performance under more practical circumstances. Stable movement, precise hazard detection, dependable Wi-Fi communication, and efficient remote monitoring via live video streaming were all demonstrated by the prototype. The system functions as intended and successfully accomplishes the goal of enhancing safety while lowering the need for human presence in dangerous environments, according to the development and testing results.

V. System Performance and Result Analysis

A number of significant metrics, such as obstacle detection accuracy, gas sensing sensitivity, temperature monitoring stability, vibration detection capability, communication delay, and overall system reliability, were used to assess the performance of the suggested IoT-enabled autonomous robot. The experiments were carried out in controlled environments that mimicked dangerous settings like high-temperature zones, gas leakage areas, and obstacle-filled pathways. This evaluation's primary objective was to assess the system's accuracy and efficiency in identifying environmental risks and reacting quickly in the event of a disaster.

When it came to identifying obstacles between 2 and 400 cm, the ultrasonic sensor demonstrated excellent accuracy. Obstacles were positioned along the robot's path at varying distances during testing. The robot successfully identified these obstacles and stopped on its own when it reached the predetermined safety distance. Reliable collision avoidance was guaranteed because the detection accuracy stayed above 95% within the effective sensing range. Environmental noise and variations in surface reflection caused some minor measurement variations at longer distances, but these variations had little effect on the system's overall performance.

When it came to identifying dangerous gases like carbon monoxide and methane, the gas sensor showed good sensitivity. When the gas concentration exceeded the predetermined threshold level during controlled testing with gas exposure, the sensor reacted in a matter of seconds and produced alert notifications. The sensor is appropriate for real-world hazard monitoring applications because the response time stayed constant. Environmental factors like humidity and sensor calibration caused slight variations in the readings. Appropriate calibration and environmental compensation methods can reduce these problems.

Additionally, the temperature monitoring system performed accurately and steadily. When the temperature sensor's readings were compared to those from conventional reference thermometers, there was very little variation. During testing, the system was able to detect an increase in temperature and promptly send warning alerts to the IoT platform. Vibrations and tilt movements were successfully detected by the MEMS sensor. In order to replicate structural instability, the robot chassis was purposefully tilted and vibrated during testing. The sensor demonstrated its value for tracking structural conditions in disaster-affected areas by accurately detecting these shifts in orientation and movement.

By monitoring the dependability and latency of sensor data transmission to the cloud platform, the IoT communication performance was assessed. Through Wi-Fi connectivity, the E microcontroller successfully transmitted the sensor readings to the cloud server. Depending on the available network strength, the average data transmission delay varied from one to three seconds. The IoT dashboard confirmed steady communication between the robot and the cloud platform by displaying the sensor values in real time through graphical updates. Additionally, the ESP32 camera module offered continuous live video streaming, enabling remote operators to keep an eye on their surroundings. Although the quality was dependent on the available internet bandwidth, the video feed maintained a respectable level of clarity and frame rate.

Overall, the hardware and software components of the integrated system worked well together. In dangerous situations, the robot reacted swiftly by halting its motion, sending sensor data for remote monitoring, and producing alerts. The experimental findings show that the suggested system effectively accomplishes its goals of enhancing safety, reducing human involvement in hazardous areas, and facilitating quicker disaster response. The system's overall performance proved to be dependable and appropriate for environmental hazard monitoring applications, despite certain limitations that were noted, such as reliance on Wi-Fi connectivity and battery life limitations.

VI. CONCLUSION

The design and development of an IoT-enabled autonomous robotic system for monitoring dangerous environments and assisting with disaster response operations was presented in this paper. In order to gather and process data in real time, the system combines an ESP32 microcontroller with several environmental sensors, such as gas, temperature, ultrasonic, and MEMS sensors. The robot can identify environmental risks and send crucial information to distant operators by fusing sensor-based monitoring with Internet of Things communication and live video streaming.

During testing, the developed prototype showed dependable performance. Accurately detecting obstacles, identifying dangerous gas levels, tracking temperature changes, and identifying vibrations or structural instability were all capabilities of the robot. Real-time monitoring and alert generation were made possible by the ESP32 microcontroller's successful processing of sensor data and its

transmission via Wi-Fi to the IoT cloud platform. By enabling live video streaming and enabling operators to visually inspect dangerous areas from a safe distance, the ESP32 camera module further improved the system.

The outcomes of the experiment verify that the suggested system increases safety by lowering the requirement for human presence in hazardous situations. Additionally, it improves response efficiency by offering timely alerts during critical situations and ongoing monitoring. The system proved to be dependable and efficient for hazard detection and monitoring despite certain drawbacks, such as reliance on network connectivity and battery capacity.

All things considered, the suggested IoT-based robotic platform provides a useful and affordable option for applications in emergency response, industrial safety monitoring, and disaster management. The system can be extended for more extensive deployments and sophisticated autonomous operations in dangerous environments with additional advancements in sensor accuracy, communication dependability, and power management.

ABSTRACT--The exponential development in cybercrime has revolutionized the criminal activities landscape, consequently requiring a fundamental shift in the way criminal justice professionals are educated. Conventional educational programs often focus on the legal framework and the basics of digital orensics, but fail to include newer technologies like Artificial Intelligence (AI),which are now essential in modern cybersecurity activities. The current paper suggests an all-encompassing and progressive AI-based cybersecurity educational framework specifically designed for criminal justice professionals.The framework is based on foundational knowledge, practical skills, and advanced AI-based methodologies. Emphasis is given to the importance of interdisciplinarity through the combination of criminal law, cybersecurity, machine learning, and real-world investigative practices. Various educational methodologies, assessment strategies, and guidelines are also presented in the current study to ensure practical relevance and applicability.The suggested framework is expected to bridge the gap between theory and practice equipping professionals with the competencies required to detect, prevent, and respond to sophisticated cyber threats effectively.

Keywords--Cybersecurity,Artificial Intelligence, Criminal Justice, Digital Forensics, Machine Learning, Curriculum Design

I. INTRODUCTION

The digital revolution has profoundly impacted the nature of crimes, and cybercrime has evolved as one of the fastest-growing crimes in the world. The criminal justice professionals are now required to investigate complex crimes related to hacking, identity theft, financial fraud, and cyberterrorism. However, the training programs are often not equipped with the technical expertise to handle these complex crimes.

Artificial Intelligence (AI) plays a vital role in the field of cybersecurity. It aids in the detection, analysis, and predictive policing of crimes. Despite the significance of AI in the field of cybersecurity, there is a lack of AI integration in the training programs for criminal justice professionals.

This paper focuses on the introduction of a progressive learning framework for the integration of AI in the training programs for criminal justice professionals in the field of cybersecurity. The framework is designed to provide a step-by-step approach to learning, from basic to advanced levels.

II. BACKGROUND AND RELATED WORK

Evolution of Cybercrime

Cybercrime has transformed from a mere hacking attempt to sophisticated cybercrimes such as ransomware, phishing, and advanced persistent threats (APTs). Cybercriminals use AI and automation technologies that make it difficult to detect and prevent sophisticated cybercrimes

B. Cybersecurity Education in Criminal Justice

The current programs are mainly centered on legal procedures and digital forensic skills. Though these are important, they do not cover current technological advancements such as AI analysis.

XXX-X-XXXX-XXXX-X/XX/$XX.00 ©20XX IEEE

C. Role of Artificial Intelligence in

Cybersecurity

The role of AI in cybersecurity is mainly through the use of machine learning and deep learning techniques, as seen in: Intrusion detection systems Fraud detection Malware analysis Behavioural analyccs These are proactive measures rather than reactive ones.

D. Research Gap

There is no framework that links AI and cybersecurity education for criminal justice professionals. This paper fills the gap.

III. PROPOSED AI-ENHANCED

CURRICULUM FRAMEWORK

A. Design Principles

The curriculum is designed according to the following principles:
Progressive Learning: Gradual increase in complexity
Interdisciplinary Approach: Integration of law, technology, and AI
Practical OrientaƟon: Emphasis on hands-on training
Scalability: Adaptable to various institutional settings

B. Three-Tier Learning Model

1) Foundation Level
Emphasizes the development of foundational knowledge:

Basics of Cybersecurity

Introduction to Criminal Law

Computer Systems and Networks

Ethical Considerations

2) Intermediate Level

Emphasizes the development of knowledge and skills:

Network Security

Digital Forensics

Data Analysis
Introduction to Machine Learning

3) Advanced Level

Focus on specialized AI applications in the field of cybersecurity:

AI-driven threat detection

Predictive policing

Cyber threat intelligence

Advanced forensic analytics

C . Curriculum Structure (Table I)

Level	Core Subjects	Skills Developed
Foundation	Cyber Law, IT Basics	Legal and Technical Awareness
Intermediate	Network Security, Forensics	Analytical Skills
Advanced	AI Security, Threat Intelligence	Predictive and Investigative Skills

IV. PEDAGOGICAL APPROACHES

A. Experimental Learning

The students will be involved in real-world simulations of cybercrime cases, which will enable practical understanding.

B. Case-Based Learning

The study of real-world cybercrime cases will enhance critical thinking skills.

C. Laboratory Training

The use of cybersecurity tools and AI frameworks will provide experOse in cybersecurity.

D. CollaboraOve Learning

Partnerships with industry experts and law enforcement agencies will provide exposure to real-world challenges.

V. AI INTEGRATION IN CYBERSECURITY TRAINING

A. Machine Learning Applications

Machine learning models can be used to identify anomalies in network traffic,potential threats.

B. Natural Language Processing (NLP)

NLP is employed in the analysis of cyber threats present in communication data, including emails and social media.

C. Predictive Analytics

AI facilitates the forecast of cyber threats utilizing past data.

D. Automation in Cybersecurity

AI-powered tools are employed to automate repetitive tasks.

VI. IMPLEMENTATION STRATEGY

A. Institutional Requirements

Qualified faculty with interdisciplinary expertise Advanced computing infrastructure Access to cybersecurity tools and datasets

B. Industry Collaboration

Partnerships with cybersecurity firms provide:

Internships
Real-world case studies
Training programs

C. Government and Policy Support

Government initiatives can support funding, standardization, and adoption of such curricula.

VII. EVALUATION AND ASSESSMENT METHODS

A. Continuous Assessment

Includes quizzes, assignments, and lab evaluations.

B. Project-Based Learning

Students work on real-world cybersecurity problems.

C. Practical Examinations

Hands-on tests to evaluate technical skills.

D. Capstone Projects

Final projects integrating AI and cybersecurity concepts.

VIII. CASE STUDY: APPLICATION OF THE FRAMEWORK

A pilot implementation of the curriculum in a training institute demonstrated improved student performance in cybercrime investigations. Participants showed enhanced ability to detect and analyze cyber threats using AI tools.

IX. BENEFITS OF THE PROPOSED FRAMEWORK

Enhanced technical competence Improved investigative efficiency Better preparedness for modern cyber threats Integration of cutting-edge technologies

X. CHALLENGES AND LIMITATIONS

High implementation cost
Lack of skilled educators
Rapid technological changes
Ethical concerns in AI usage

XI. FUTURE DIRECTIONS

Future enhancements may include:
Integration of blockchain and quantum security
Development of adaptive AI learning platforms
Global standardization of cybersecurity Education

XII. CONCLUSION

The increasing complexity of cybercrime necessitates a modernized and technology driven approach to training criminal justice professionals. This paper presents a comprehensive AI-enhanced cybersecurity curriculum using a progressive learning framework. By integrating foundational knowledge with advanced AI applications, the framework addresses current educational gaps and prepares professionals for future challenges. Adoption of this model can significantly improve the effectiveness of cybercrime prevention and investigation.

ACKNOWLEDGMENT

The authors acknowledge the contributions of academic institutions and cybersecurity professionals in shaping this research.

Abstract - *This project demonstrates the design and implementation of an IoT-based vehicle safety & accident detection system that aims at improving road safety through real-time monitoring and sending emergency alerts. The sensors integrated into the system include a vibration sensor to identify accidents, a GPS module to determine the precise coordinates, an ultrasonic sensor to track obstacles, and environmental sensors to evaluate surrounding conditions, all controlled by an Arduino microcontroller. Finally, there is the regular mode, in which the system continuously monitors the vehicle's parameters and occasionally sends location data via LoRa technology, using communication tools that are well suited to IoT networks due to their long-range and energy-efficient communication. If a sudden collision occurs, an accident is automatically recognized, the exact GPS coordinates are received, and an emergency notification is sent to the monitoring center and the cloud platform. The resulting information is saved in the Firebase cloud storage, allowing for real-time tracking, distant observation, and historical data analysis. Compared to conventional high-bandwidth communication protocols, LoRa presents advantages in energy conservation, economic efficiency, and reliability in connectivity within remote areas. The proposed solution offers a practical, scalable approach to intelligent transportation systems and reduces emergency response duration while enhancing vehicular and public safety***.**

I .INTRODUCTION

Traffic collisions are one of the leading causes of injuries and deaths in the world and have social, economic and safety implications. The postponed medical aid, lack of immediate vehicle tracking, and poor communication systems often exacerbate the severity of consequences resulting from accidents. The rapid growth in the number of vehicles has increased the traffic jams, and there is a great need for the smart transportation system that can track the condition of the vehicles round the clock and provide timely notifications in case of any emergencies. The rise of the internet of things (IoT) has opened up new avenues for integration of smart sensors and wireless communication technologies with cloud platforms to improve vehicular safety and emergency response systems. The suggested initiative puts great emphasis on the design and execution of IoT based vehicular safety and accident detection system that ensures real-time surveillance, accurate accident identification, and widespread communication. Sensors and communication modules are combined with a microcontroller to create a small yet highly efficient safety unit that is integrated into a vehicle. There is a vibration sensor to identify abrupt 'hits' or unusual shocks to detect a collision. Monitored through the GPS module are the overall location of the vehicle, velocity, and time, thus accurately positioning the vehicle in the event of an emergency. In this case, an ultrasonic sensor is instrumental in establishing obstacles by determining the distance from the vehicle to nearby objects to avoid collisions. Additional information on vehicle analysis capabilities may be offered by including other relevant environmental monitoring modules, such as sensors for temperature and humidity.

An ESP8266 microcontroller serves as the main processing unit of the system, coordinating data acquisition, processing, and transmission for all linked components. It is done by comparing the collected data against the set threshold values, and either the vehicle

is functioning normally, or an uncommon event occurs in the car. During normal operation, the system also sends out updated location data on a regular basis to track the vehicle in real time. However, when a significant vibration or impact is detected, the system immediately switches to emergency mode and generates an alarm message containing vehicle identification information and precise GPS coordinates. LoRa (Long Range) technology is used for the project's wireless communication, making it most appropriate for the IoT application due to its low power consumption, long-distance transmission, and cheap costs. However, contrary to the cellular networks that require substantial infrastructure and are costly to maintain, LoRa can transmit short packets of information over long distances using little power. This makes it suitable for vehicle tracking systems that send small amounts of data regularly. The information is stored for later use and is also accessible for real-time monitoring and historical use.

Cloud storage is integrated into the system to improve its functionality by enabling remote access to vehicle information via a mobile or online interface. Every emergency message, location, or sensor data may be viewed from any location, and emergency services or authorized individuals can take the appropriate action. Considering future growth in terms of interaction with smart city structures and traffic control agencies is made easy by this unified data management approach.

Providing a dependable, energy-efficient, and scalable solution for vehicle safety is the goal of this project. Utilizing cloud technology, IoT sensors, GPS tracking, and long-distance communication efficiently maximizes emergency vehicle monitoring, smart road system development, and accident reaction times.

LoRa (Long Range) is a low-energy wireless communication method designed for Internet of Things (IoT) applications that require long-range data transfer using minimum energy. It operates on the unlicensed Industrial, Scientific, and Medical (ISM) frequency bands of 433 MHz, 868 MHz, and 915 MHz, depending on the country's regulations. Due to its ability to connect devices over long distances with minimal power consumption, LoRa has found wide application in smart city infrastructure, environmental monitoring, agriculture, industrial automation and vehicle tracking. Unlike traditional short-range wireless communication technologies such as Wi-Fi or Bluetooth, which are designed to deliver high data rates, LoRa has been optimized for the reliable and efficient transfer of small data packets over long distances.

Chirp spread spectrum (CSS) modulation is the fundamental technology of LoRa. This modulation technique uses chirp pulses, which are characterized by a gradual increase or decrease in frequency over time, to create signal spreading. Because of this spreading technique, the system is resistant to noise, interference, and degradation, making LoRa extremely dependable in demanding settings like cities or rural areas. Given that the signal can be consistently recognized even below the noise floor, this allows for long-distance communication with low transmission power.

Firstly, LoRa communication mainly takes the form of a star network, whereby several end devices (sensors or vehicular units) connect directly to a central gateway. The information is relayed to a cloud server via an internet link by the gateway. It reduces device complexity and energy consumption because the last devices do not have to communicate with each other directly. Instead, they send information to the gateway either at set intervals or when an incident occurs. Communication parameters like spreading factor, bandwidth, and coding rate can be adjusted to optimize data rate, range, and power consumption. The larger the spreading factor, the more extended the range and the lower the data rate; conversely, the smaller the spreading factor, the faster the data transfer over shorter distances.

When a LoRa-capable device is ready to transmit data, it first collects the required sensor information from the microcontroller. The information is then encoded and modulated using Chirp Spread Spectrum before being transmitted as a radio signal. The signal is received by the gateway, decoded, and routed to cloud services or a network server. In other cases, confirmation messages can be initiated to ascertain a successful receipt. LoRa devices can be in the low-power or sleep mode and only turn on when data transmission is taking place, significantly enhancing battery life.

II .LITERATURE SURVEY

Kumar, A., & Singh, B. [1] The rate of road accidents has gone up in many developing parts of the world with rapid growth of cities leading to massive loss of life and property. The existing traffic monitoring systems suffer from the limited communication range and the use of centralized systems, which makes it impossible to provide real-time data. According to the authors, cellular communication and short-range wireless technologies traditionally used suffer from high vehicle density, resulting in slower emergency response and insufficient accident prevention. This research points out the importance of adopting long-distance, energy-efficient communication technologies for instant data sharing between each other and the infra structure. In doing so, the study contributes to the development of connected vehicle technologies that can better inform drivers, reduce accidents, and promote road safety.

Li, J., Wang, Y., & Zhang, L. [2] Road safety and traffic congestion have grown to be significant problems in smart cities where the number of vehicles is increasing quickly.Conventional car tracking and communication systems often use GPS and cellular networks, which can be slow and expensive to operate, especially in places with poor signal strength. The authors of the study investigate a number of communication technologies that provide long-distance connectivity without requiring continuous data costs. They emphasize the ability of low power wide area network (LPWAN) protocols, such as LoRa, to deliver real-time emergency warnings and telemetries.

Sharma, R., & Gupta, P. [3] In intelligent transportation systems, enhancing traffic safety and avoiding accidents rely on the dependability and speed of data transmission. This study highlights the challenges that short-range technologies, like Wi-Fi and Bluetooth, face in high-speed vehicle settings because of unstable connections and limited range. Moreover, cellular networks can lead to unexpected delays in areas with weak signal strength or when the network is heavily congested. The authors propose that low-power, long-range communication technologies can be combined with cloud-based systems to bridge these gaps. By using remote monitoring, efficient data transmission, and prompt delivery of emergency alerts, these technologies can reduce response times and provide drivers with essential information about their surroundings.

Hussein, M., & Alsaqour, R. [4] The increasing number of yearly road accidents highlights the shortcomings of current traffic safety initiatives. Traditional monitoring systems mainly rely on human input for reporting accidents, which often results in delayed emergency responses. This research looks at how vehicles equipped with sensors connected to Internet of Things (IoT) systems can automatically report incidents. Devices such as accelerometers, GPS, and environmental sensors can provide real-time information about the situation when an incident occurs. In addition to robust wireless communication and cloud-based processing, the system is capable of producing real-time alerts and location-based information for emergency personnel. The findings show that systems equipped with IoT technology can significantly reduce the time it takes for emergency services to respond and enhance the effectiveness of road safety measures.

Patel, K., & Mehta, S. [5] Because of the rapid expansion of vehicle networks and intelligent transportation systems, traditional vehicle monitoring approaches have shown limited effectiveness in handling real-time data transmission in scenarios involving high mobility. This research highlights that conventional GPS and GSM tracking systems face delays and unreliable signal reception in remote or obstructed areas. The authors examine the use of low-power wireless technologies, which can reduce dependence on cellular networks and improve the reliability of location updates and emergency alerts. Their study emphasizes that using efficient communication protocols such as LoRaWAN enables long-distance data transmission with low power consumption, thus improving accident management and streamlining traffic flow. The study shows that modern vehicle safety technologies should incorporate strong communication systems to overcome the shortcomings of conventional tracking methods.

Zhao, H., & Li, X. [6] Road safety remains a major global concern due to the high frequency of accidents and the generally delayed emergency response. This literature looks at intelligent vehicle systems that use sensor networks for automatic crash detection. The authors show how combining real-time accelerometer and location data with wireless data transmission can enhance drivers' awareness of their surroundings and the effectiveness of remote monitoring centers. They also mention that short-range radio technologies, though useful for local communication, are unable to provide wide coverage in larger urban or rural areas. The study therefore recommends using multi-level communication strategies that integrate local vehicle alerts with broader dissemination through cloud services and large-scale networks. The findings show that intelligent vehicles equipped with sensor fusion and automated warning systems significantly improve detection speed and reduce critical response time.

III. PROPOSED METHODOLOGY

The proposed method for the IoT-based vehicle safety and accident detection system is designed to offer real-time monitoring, quick identification of accidents, reliable long-range communication, and a centralized data storage solution. The system's architecture is organized in layers, including the sensing layer, processing layer, communication layer, and cloud monitoring layer. Each layer performs a specific function to ensure the smooth and efficient operation of the entire system.

The sensing layer includes multiple sensors within the vehicle to continuously monitor different parameters. The vibration sensor identifies quick jolts or abnormal hits that may indicate a collision. It operates by detecting thresholds, assessing the strength of vibrations, and comparing them to predefined levels. The GPS module continuously collects real-time location information such as latitude, longitude, speed, and timestamp. This ensures that the precise location of the vehicle is always available. The ultrasonic sensor

measures the distance between the vehicle and nearby obstacles, helping to identify potential collision dangers. In addition, environmental sensors such as temperature and humidity monitors keep track of surrounding conditions, which may improve vehicle diagnostics and data analysis. Each of these sensors produces digital signals that are received by the central microcontroller for further processing.The car parking system is done automatically detect and information carry over for users. The auto bill generation process provide the user friendly process.

The processing layer revolves around an Arduino microcontroller, which acts as the system's central component. The microcontroller initializes all connected modules during system startup and regularly collects sensor data at set intervals. The collected data is analyzed using logic that is programmed through the Arduino IDE. Under normal operating conditions, the system regularly prepares and formats location data packets for transmission. However, if the vibration sensor detects an impact above the threshold level, the microcontroller quickly switches to emergency mode. In this state, it collects the latest GPS coordinates, assigns a unique event ID, includes time information, and generates an important emergency alert message. This package contains essential details such as the vehicle identification, accident status, and precise location information. The data packet is intended to be as compact as possible while including all necessary information for a quick response.

The communication layer uses LoRa (Long Range) technology to send data wirelessly. LoRa is selected due to its low power consumption, long-range communication capabilities, and compatibility with IoT-focused systems. The microcontroller sends the organized data packet to the LoRa module, which adjusts the signal using the Chirp Spread Spectrum (CSS) technique. The adjusted signal is transmitted to a LoRa gateway located within the coverage area. In normal conditions, routine tracking updates are transmitted at set intervals to reduce network traffic and save power. In emergency situations, quick alerts are sent out to ensure fast communication. The gateway receives the transmitted data and sends it to the cloud server through an internet connection.

The cloud monitoring layer is implemented through Firebase cloud storage. The collected data is stored in a structured database format, enabling real-time monitoring and the maintenance of historical records. Authorized users can access the data through a web or mobile interface, allowing them to track vehicle movements and receive immediate alerts regarding accidents. The cloud system also logs environmental and operational data for future analysis. This integrated storage approach ensures data accessibility, scalability, and the ability to monitor remotely.

Power management methods are used to ensure system efficiency. The LoRa module operates in a low-power mode when not in use, and the data transmission rate is modified to reduce unnecessary energy consumption. The modular software design makes it easy to maintain and expand for future improvements, such as AI-based accident prediction or automatic emergency alerts.

In addition to real-time monitoring and the delivery of emergency alerts, the proposed method also incorporates aspects of reliability, scalability, and security to ensure successful application in real-world scenarios. Cloud-based structured database management allows for the organized storage of vehicle logs, accident records, and tracking data to facilitate analysis.

This method also supports future integration with mobile applications and smart city systems, allowing officials to analyze traffic patterns, identify areas with high accident rates, and implement preventive measures.

Fig.1

Advantages :

Real-Time Accident Detection

Using a vibration sensor, the device swiftly identifies abrupt hits and, without any human input, immediately sounds an emergency alert.

Accurate Location Monitoring

Accident locations can be quickly identified thanks to the GPS module's precise latitude and longitude information.

Communication Over Distance

LoRa technology is ideal for both urban and rural settings since it enables data transfer over several kilometers.

Minimal Energy Use

Optimizing transmission intervals in conjunction with LoRa guarantees low battery use, increasing system efficiency.

Economical Resolution

The suggested approach lowers infrastructure and operational expenses in comparison to cell-based systems.

Cloud-based monitoring

Real-time data storage, remote access, and historical record preservation are made possible by connecting to the Firebase cloud.

IV. SYSTEM ARCHITECTURE

The suggested IoT-based vehicle safety and accident detection system is designed with a unified, multi-level structure that ensures continuous monitoring, intelligent decision-making, reliable communication, and centralized cloud management. The foundation of the architecture is the sensing layer, which includes a vibration sensor to detect sudden impacts, a GPS module to gather real-time location information, an ultrasonic sensor to measure the distance to obstacles, and environmental sensors to monitor temperature and humidity levels. These sensors continuously generate real-time data and transmit it to the processing layer, where the Arduino microcontroller acts as the primary control component. The microcontroller begins by initializing all hardware components, collects sensor data at regular intervals, and evaluates the information using pre-set logic thresholds to determine whether the vehicle is operating normally or experiencing an emergency. During normal operation, the controller creates structured data packets that contain vehicle identification details and routine location updates. If the system detects unusual vibrations that may indicate an accident, it immediately switches to emergency mode, retrieves the latest GPS coordinates, and generates a high-priority alert.

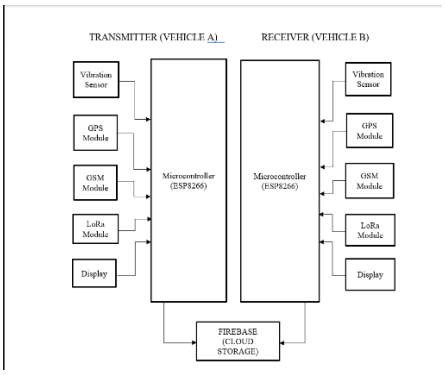

Fig.2

The proposed IoT-based vehicle safety and accident detection system's architecture comprises several essential components that work together to provide real-time monitoring and emergency alert transmission. The primary components used are the ESP8266 microcontroller, vibration sensor, GPS module, ultrasonic sensor, LoRa module, LoRa gateway, and Firebase cloud service. The vibration sensor identifies sudden shocks or strong impacts that may indicate an accident. The GPS module continuously provides current location data, such as latitude, longitude, speed, and time. The ultrasonic sensor measures the distance between the vehicle and nearby obstacles to help identify potential collision risks. The ESP8266 acts as the central processing and control component of the system, linking all these sensors.

The process is straightforward and efficient. The code is created and uploaded to the ESP8266 using the Arduino IDE. When powered on, the ESP8266 initializes all connected modules and continuously gathers sensor data. When functioning normally, it collects GPS location information and sends routine updates through the LoRa module. When the vibration sensor detects an impact that exceeds the predefined threshold, the ESP8266 quickly identifies it as an accident and retrieves the latest GPS location. This data is bundled into a packet and transmitted via the LoRa module to a LoRa gateway, which subsequently forwards it to the Firebase cloud platform for storage and monitoring. The cloud service provides immediate monitoring and visibility of emergency alerts through a web or mobile interface. This method enables the components to work together for automatic accident detection, enhanced communication, and reliable remote monitoring, without the need for temperature or humidity sensors.

V. MODULE DESCRIPTION

1. Sensor Module

The sensor unit comprises a vibration sensor, GPS module, and ultrasonic sensor. The vibration sensor detects sudden shocks or strong impacts and helps identify accident scenarios. The GPS module continuously tracks the vehicle's current location by providing information on latitude, longitude, speed, and time. The ultrasonic sensor measures the distance between the vehicle and nearby obstacles by using reflected echo pulses, which helps in detecting potential collisions. This module is responsible for collecting all necessary real-time information from the vehicle's environment.

Fig.3

2. Processing Module (ESP8266 Controller Module)

The ESP8266 microcontroller serves as the central processing unit of the system. It collects data from all connected sensors, evaluates the information based on predefined logic, and determines whether the vehicle is in a normal or critical condition. The software was developed using the Arduino IDE and then transferred to the ESP8266. The controller oversees tasks like starting up sensors, evaluating thresholds, identifying accidents, and creating data packets for sending.

Fig.4

3. Communication Module (LoRa Module)

The communication module uses LoRa technology to send data wirelessly across long distances. Once the ESP8266 generates a data packet containing location and accident details, the LoRa module transmits it to a LoRa gateway. LoRa is selected because of its low power consumption and long-range communication capabilities, which make it well-suited for IoT applications in vehicles.

Fig.5

4. Gateway Module

The LoRa gateway receives data from the vehicle unit and forwards it to the internet. It acts as a connection between the vehicle's LoRa module and the cloud service. This ensures that data can be accessed from any remote location.

5. Cloud Monitoring Module (Firebase Platform)

The cloud module uses Firebase to save real-time vehicle data, accident alerts, and tracking information. The stored data can be accessed through web or mobile applications for viewing and analysis. This module enables remote monitoring and quick emergency response.

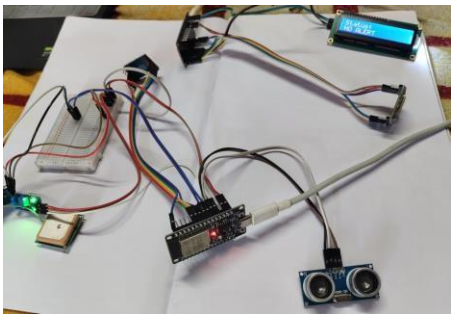

Fig.6

VI. EXPERIMENTAL RESULTS

VII. CONCLUSION AND FUTURE WORK

The proposed IoT-based vehicle safety and accident detection system demonstrates a reliable and efficient method for monitoring vehicles and sending instant emergency alerts using modern wireless communication technologies. By integrating the ESP8266 microcontroller with a vibration sensor, GPS module, ultrasonic sensor, and LoRa communication module, the system ensures accurate accident detection, obstacle monitoring, and broad data transmission. The vibration sensor precisely identifies abrupt impacts, the GPS module provides accurate location data, and the ultrasonic sensor enhances safety by detecting nearby obstacles. The ESP8266 smartly analyzes all collected data and transmits key information through LoRa to a gateway, which forwards it to the Firebase cloud platform for real-time tracking and storage. This design ensures low power consumption, wide coverage area, and reliable communication, even in remote locations where traditional cellular networks may have difficulty functioning properly. The system reduces emergency response times by automatically sending accident alerts along with exact location coordinates, which improves road safety and may save lives. In addition, cloud storage enables continuous data recording, analysis, and remote access, making the system scalable and suitable for smart transportation applications. The full implementation shows that combining IoT, embedded systems, and long-range wireless communication provides a cost-effective and efficient solution. In future developments, the system could be improved by adding more intelligent features to increase accuracy, automation, and scalability. More advanced algorithms, like machine learning models, can be used to more accurately distinguish between small vibrations and serious accidents, which helps in minimizing false alarms. Integrating with a mobile app that offers real-time alerts, live vehicle monitoring, and automatic emergency contact features can enhance user engagement and reaction times. The system can be extended to manage multiple vehicles via a centralized dashboard, enabling fleet management and large-scale monitoring. Including a camera module to record visual evidence during accidents and integrating automatic alerts to emergency services via SMS or phone calls can enhance the effectiveness of emergency response systems. Future versions might also offer hybrid communication support by integrating LoRa with 4G or 5G networks to guarantee continuous connectivity in any environment. Power-saving methods, solar-powered charging, and a compact hardware design can improve portability and extend usage over time. With these enhancements, the system has the potential to develop into a complete smart vehicle safety platform that can be integrated into intelligent transportation systems and smart city infrastructure.

ABSTRACT : Social media is one of the major online platforms that have greatly impacted the formation of relationships between governments and their citizens in contemporary democratic countries across the globe. Social media platforms such as Facebook, Instagram, X (Twitter), YouTube, and WhatsApp have greatly impacted the dissemination of information regarding politics and governments in India. This study is aimed at finding the impacts of social media, especially in relation to governments in India. This study is based on the impacts of social media, especially in relation to awareness, democratic participation, relationships with governments in India, and dissemination of accurate and inaccurate information. This study is mainly based on a descriptive and empirical research approach. A major focus is given to quantitative data analysis in this research. The data is collected through a questionnaire containing 30 questions aimed at analysing the patterns. The respondents in this research are chosen from diverse age groups and professions. This ensures that diverse opinions are included in this research.

INTRODUCTION : The impact of social media is seen in the relationship between governments and citizens in democratic countries. This study has been conducted with reference to India and its social media sites such as Facebook, Instagram, X, YouTube, and WhatsApp. The impact of social media has been studied with reference to its impact on the governance and citizens of the country. The study has been conducted by analysing the impact of social media on the awareness and communication of the citizens. The study has been conducted by using the descriptive and empirical research methodology. Quantitative research has been conducted by using statistical tools. The data has been collected from people belonging to different age groups and professions. The impact of social media has been studied as positive and negative.

REVIEW OF LITERATURE

1. **Raju (2025)** looked at how platforms like Facebook, Twitter, and Instagram shape political awareness. The study found that social media plays a strong role in improving political knowledge, especially among young people.

2. **Tiwari & Singh (2023)** explored social media use in India after COVID-19. They found that platforms like WhatsApp and Twitter became important tools for communication and helped increase political participation.

3. **Velmurugan (2025)** examined how social media affects youth involvement in democracy. The study showed that it raises awareness and encourages young people to take part more actively.

4. **Kumar & Yadav (2024)** studied the impact of social media on political engagement and found that it plays a key role in increasing participation.

5. **Kanaka Laxmi & Chaturvedi (2024)** found a strong connection between social media use and higher levels of political participation.

6. **Nazim Sha & Rajeswari (2018)** showed that social media strongly influences the political decisions of young people in India.

7. **Ranjan (2023)** highlighted the growing importance of social media in election campaigns, where leaders use it to connect directly with the public.

8. **Chatterjee & Dutta (2024)** found that social media allows leaders to communicate directly with people, increasing their influence.

9. **Jakeschetal (2021)** showed that organized groups use social media platforms to shape political discussions and trends.

10. **Dashetal (2021)** found that influencers on social media can increase political divisions.

OBJECTIVES

1. To understand how social media plays a role in shaping public awareness and opinions about governance in India.

2. To analyze the influence of social media platforms on citizen participation in democratic processes.

3. To examine how social media affects communication between government institutions and the public.

4. To identify both the positive and negative impacts of social media on governance and public decision-making.

5. To evaluate the role of social media in spreading information as well as misinformation related to governance issues.

METHODOLOGY

This study adopts a descriptive quantitative research design to examine the impact of social media usage among youth in India. The research is analytical in nature and is based on primary data collected through an online survey using

Google Forms. A convenience sampling technique was used, where respondents were selected based on their availability and willingness to participate. The survey was distributed online, enabling quick data collection from social media users.

The total sample size was 151 respondents, with 48.7% male and 50.7% female participants. In terms of age, 50% were below 18-25 years, while the remaining respondents were distributed across higher age groups. The study also examined platform usage, where WhatsApp (74%) and YouTube (70%) were the most used, followed by Instagram (64.7%), Facebook (24%), and Twitter (8%). The questionnaire included yes/no questions, Likert scales, rating scales, and multiple-choice questions. Data were analyzed using correlation analysis to understand the relationship between social media usage and its impact.

HYPOTHESIS

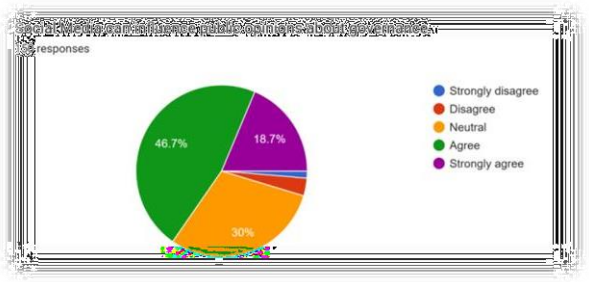
H_0 (Null Hypothesis):

Social media has no significant influence on public opinion regarding governance.

H_1 (Alternative Hypothesis):

Social media has a significant influence on public opinion regarding governance.

ANALYSIS AND INTERPRETATION



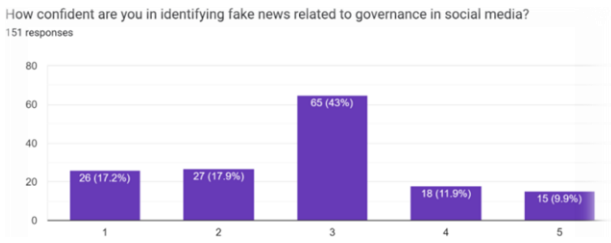


Chart 1 demonstrates the opinions of the respondents regarding the impact of social media on public opinion concerning governance. From the chart, it is evident that the majority of the respondents have a positive opinion concerning the statement. Almost half of the total respondents (46.7%) replied with the choice of "agree," and 18.7% replied with the choice of "strongly agree," which demonstrates that more than 65% of the total participants are acknowledging the role of social media as crucial in this context. Furthermore, 30% of the total participants are neutral regarding the statement. It is evident that only a very small percentage of the total participants have expressed negative opinions concerning the statement. The distribution demonstrates the inclination of the participants towards the statement in the context of its truthfulness.

	How confident are you in identifying fake news related to governance in social media?	Social Media can influence public opinions about governance.
How confident are you in identifying fake news related to governance in social media?	**1**	
Social Media can influence public opinions about governance.	**0.015037332**	**1**

Chart 2 shows the confidence levels of the respondents regarding their ability to identify fake news related to governance through social media. The results show that the highest percentage of respondents (43%) falls at mid-confidence level (rating 3). The confidence levels of 1 and 2 also contribute significantly to the results. The results for rating levels 4 and 5, representing high confidence levels, are relatively low. This shows that most people have low confidence levels for identifying fake news, and many lack confidence. This also shows that there is still some problem with fake news online and that more education is needed for people using social media.

The analysis and interpretation of this survey show that the majority of the people think that social media plays an important role in the opinion of the public regarding governance, but only a few people disagree with the idea. However, the level of confidence in the ability of people to recognize fake news regarding governance is average, as most people show an average level of confidence in the matter. Furthermore, the relationship between the level of confidence in the ability of people to recognize fake news regarding governance and the influence of social media on the matter is extremely low, as the correlation coefficient, i.e., r = 0.015, shows that the two variables have almost no relationship with each other.

FINDINGS

1. The study was able to prove that social media indeed has a perceived influence on the opinion of the public regarding governance, as seen in the consensus of the majority of the respondents.
2. The respondents are moderately confident in identifying fake news, which proves that there is ambiguity in this area.

3. The relationship between the confidence level of the respondents in identifying fake news and the perceived influence of social media was found to be negligible, as seen in the value of r = 0.015.
4. The study was able to prove the alternative hypothesis that social media indeed has an influence on the opinion of the public regarding governance, as the null hypothesis was rejected.

SUGGESTIONS

Based on the findings of the study, some of the recommendations that can be made include promoting digital and media literacy through awareness, promoting fact-checking through cooperation with various entities, promoting responsible social media use by checking the information before posting, promoting transparency in the government by posting correct information, developing policies that deal with misinformation without compromising freedom of expression, and promoting accountability in the platforms by developing algorithms that help eliminate fake news and promote correct information.

CONCLUSION

The study has concluded that the social media plays an important role in the creation of opinions among the people and the creation of awareness among them regarding the governance in India. Most of the people are aware of the role of the social media in the democratic participation of the people and the communication between the people and the government. Therefore, the study supports the alternative hypothesis that the social media plays an important role in the creation of awareness among the people regarding the governance in India. The social media like WhatsApp, YouTube, and Instagram plays an important role in the creation of awareness among the people regarding the governance in India by spreading the information and encouraging the people towards the governance in India. However, the study revealed that the people are concerned about the identification of the fake news as they have shown only a moderate level of confidence regarding the identification of the information

An Empirical Study On The Influence Of Customer Feedback On Online Purchase Behavior In The FMCG Sector

Dr.A.Elaiyaraja[1], Harini.S[2], Harshini[3].V, Harini S[4], Brindha.M[5]

[1]Assistant Professor , [2,3,4,5]Students I MBA

[1,2,3,4,5]Department of Management Studies, Panimalar Engineering College, Chennai, India

Abstract: The paper explores the role of customer feedback in influencing the behavior of individuals in purchasing products online, especially in the fast-moving consumer goods sector. The reviews and ratings, which are basically comments from other customers, help build some amount of trust, I suppose, and remove some amount of ambiguity in the decision-making process. It feels as though without this, the entire online shopping scenario would be riskier for everyone. The research design used was stats, including descriptive stats and chi-square tests, and correlation to establish the relationship. From the data, it's evident that most consumers do look at the feedback before pressing the 'purchase' button, yeah. This part of the paper was highlighted because it seemed quite reliable. Feedback is linked with the choice of products in a positive manner, if you will, and helps guide the decision. It's not clear if this is the only factor, though, and if it's the only factor, then it does explain the reliance on this in the online scenario**.**

Key words:
Customer Feedback, Online Purchase Behavior, FMCG Sector, Consumer Satisfaction, Reviews and Ratings, Purchase Intention, Consumer Trust, E-WOM, Product Selection, Online Shopping

1. Introduction

The ever-increasing growth of e-commerce has significantly changed the pattern of consumer spending, especially in the Fast Moving Consumer Goods (FMCG) segment. FMCG products, like food products, personal care products, and household essentials, are usually bought in physical stores. However, due to the widespread use of smartphones, the proliferation of the internet, and advancements in technology, people are increasingly adopting the internet as a platform for making purchases. Online shopping is the most popular among the new generation of consumers due to the benefits of time management and the availability of a wide range of products and price comparison.

Customer feedback is an important factor in the changing pattern of consumer spending in the digital age.

Reviews, ratings, and comments from previous customers are referred to as customer feedback. It is a reliable source of data for potential customers. It acts as e-word-of-mouth for customers to evaluate their overall satisfaction, performance, and quality of a product. Although negative feedback may raise certain questions for customers and may discourage them from purchasing a certain product, positive feedback is likely to increase trust and purchase intention. Moreover, customers can quickly compare a product and form opinions with the help of ratings. In particular, in the case of FMCG, customer feedback is significant for customers to reduce uncertainty in purchasing a product due to certain factors such as low costs. Customers often use other people's experiences before making snap decisions regarding purchases.

Moreover, the extent and power of customer feedback have been enhanced due to the rise in prominence of digital platforms and social media as well. With an emphasis placed on consumer trust, perception, and buy intention, this study has attempted to scientifically investigate how customer feedback impacts online buy behavior in the FMCG industry. Customer feedback plays an important role in reducing uncertainty, which impacts decision-making, particularly in the FMCG industry, as this is an industry where products are regularly purchased and extremely inexpensive as well. Before making hasty purchases, consumers often rely on the experiences shared by other consumers, particularly in an online platform, as it is not possible to physically examine the product in an online platform as well. Moreover, the extent and power of customer feedback have been enhanced due to the rise in prominence of digital platforms and social media as well.

2. OBJECTIVES OF THE STUDY

- To examine the role of customer feedback on the online purchasing behavior of the FMCG industry
- To examine the role of positive customer reviews on the purchasing decisions of consumers
- To examine the role of negative reviews on the purchasing decisions of internet shoppers
- To ascertain the relationship between customer feedback and purchase intention
- To ascertain the extent of the role of reviews prior to

the purchase of FMCG products online
- To examine the role of electronic word of mouth on the purchasing decisions of consumers

3. LITERATURE REVIEW

G. Badalar Al Mughairi, Karim A. M., and Karim A.M. conducted research on the aspect of customer satisfaction in the electronic platform concerning the FMCG industry from a global perspective. The findings of the research indicated that the aspect of customer satisfaction between customers is largely influenced by the behavior of the consumer, the usage of the electronic channel, the availability of the products, and the communication strategy.

Jain, M., and Jain, N. (2023) conducted research on the purchase of the electronic products of the FMCG industry. In this research, we analyze the data concerning the preference of the consumer towards the electronic channel, as well as the influence of the behavioral and demographic aspects of the consumer, using the statistical tools.

According to Helen, J., and V: D selvi (2022), the product, price, promotional, and psychological factors are the main factors influencing the purchase of the FMCG products for the consumer.

Najah, K. A., Jenita, A. M. A, carried out a research on the impact of the integrated marketing communication strategy on the buying behavior of the consumer, which stated that the consumer would be induced to be aware of the brand and would trust the product. The consumer buying behavior towards the FMCG products through the Digital Marketing was studied by Giri et. al., 2026. According to the research, the pricing offers have the strongest impact on the consumer buying behavior, followed by convenience, while the impact of the social media influencer on the consumer buying behavior is the least.

Saraswat, D., Singh, Y., and Vidani, J. (2024) have compared the awareness of consumers and the purchase behavior of FMCG products in the market. The research study revealed that there is a difference in the behavior of consumers because of factors such as accessibility and affordability.

Mukherjee, S. Das, M. K and Chakraborty, T. K.(2023)m in their research study on viral marketing during FMCG reported that commitment to a brand (brand awareness) has a positive impact of purchase intention with mediating function being performed by brand loyalty.

Maheswari, S. (2023), Artificial intelligence and marketing of FMCG: the new age tools, Journal of Management Insights. The study has confirmed the fact that AI-based strategies have a higher influence on consumer behavior.

Ahuja, V., and Tabeck, P. S. (2024) conducted a study on the influence of social media marketing on the FMCG sector. The study concluded that social media has a positive influence on consumer positioning, relationships, and trust.

Saeed & Sharma published this study in 2026, comparing the level of satisfaction of the customers with quick commerce as opposed to the regular e-commerce models. It seems like the speed of delivery is what actually makes the people satisfied with the quick commerce, you know, because everything comes at such a fast pace. In the case of regular models, the prices seem to be the bigger issue, at least according to what they say.

4. RESEARCH METHODOLOGY

4.1 Research Design

This research is based on the descriptive and analytical research design to understand customer satisfaction in the FMCG industry. The research is quantitative in nature because it is based on numerical data and analyzed through statistical tools.

4.2 Sample Size and Sampling Technique

This research is based on 60-70 respondents. The sampling technique is convenience sampling. In this technique, the respondents are selected on the basis of ease of access.

4.3 Data Collection Method

Primary data is collected through the survey method of research. The questionnaire is structured and consists of close-ended questions.
Secondary data is collected through various articles and online sources.

4.4 Data Analysis Techniques

Data is analyzed through various statistical tools such as:
- Descriptive Analysis (Mean and Percentage)
- Chi-square Test
- Correlation Analysis

The results are presented in a tabular form for better understanding.

1.1 Demographic Profile

The study takes into consideration factors such as age, gender, education, occupation, and income to determine the demographic characteristics of respondents.

1.2 Measurement Scale

A Likert scale is used to measure variables such as customer satisfaction, product quality, etc. The Likert scale ranges from 1 to 5.

1. DATAANALYSIS AND INTERPRETATION

Table 5.1

TABLE SHOWING THE AGE OF THE RESPONDENTS

Age Range	Frequency	Percentage
18-25	60	84.5%
26-35	3	4.2%
36-45	7	9.9%
46-and above	1	1.4%

Interpretation:

The age distribution of the respondents has been shown in the table below, i.e., Table 2. It has been noted that the majority of the respondents, i.e., 60, or 84.5%, fall in the age group of 18-25. The second highest number of respondents, i.e., 7, or 9.9%, fall in the age group of 36-45. Three, or 4.2%, of the total respondents fall in the age group of 26-35, whereas only one, or 1.4%, of the total respondents fall in the age group of 46 or above. It has clearly been indicated that the majority of the respondents fall in the age group of 18-25.

DESCRIPTIVE ANALYSIS

Table 4.2 Frequency and Percentage of Customer Satisfaction

Response Option	Frequency	Percentage (%)
Very Satisfied	18	30.0%
Satisfied	22	36.7%
Neutral	10	16.7%
Dissatisfied	6	10.0%
Very Dissatisfied	4	6.7%
Total	60	**100%**

Interpretation:
From the table, it is clear that the majority of the respondents are satisfied (36.7%) and very satisfied (30.0%) with FMCG products, implying that the products have a high level of consumer satisfaction. The number of respondents who are neutral (16.7%) is significantly smaller in comparison to the number of respondents who are dissatisfied or extremely dissatisfied. This implies that the general consumer perception of FMCG products is positive.

CHI-SQUARE ANALYSIS

Table 4.3 Crosstabulation (Gender vs Satisfaction)

Gender	High Satisfaction	Low Satisfaction	Total
Male	20	10	30
Female	20	10	30
	40	Total	60

5. SUGGESTIONS

•Businesses should focus on enhancing product quality to increase customer satisfaction.

•Businesses should be fair in pricing to attract more customers.

•FMCG businesses should regularly survey their customers to understand customer needs.

•Value and quality should be given importance in marketing strategies.

•Businesses should focus on customer retention to maintain long-term relationships with customers.

6. Conclusion

The customer satisfaction in FMCG businesses is quite high, as indicated in the study. The study shows that price perception is the second most important factor in customer satisfaction, after product quality. The study has shown that quality has a high correlation with customer satisfaction, which means that enhancing product quality will improve customer satisfaction to a large extent. Hence, to maintain customer satisfaction, FMCG businesses should focus on enhancing product quality.

To Study A Social Media Influencers On Gen Z Purchasing Behavior Pattern Towards Skin Care Products In Chennai City

Mirudula[1], J. Pavithra[2], C. Ranjana[3], K. Vijayalakshmi [4]

[1, 2, 3, 4] MBA Student, Panimalar Engineering College, Chennai-600 123.

ABSTRACT

This study examines that to analysis, influence that social media influencers have had on the buying decisions of Gen Z consumers in Chennai, India. concerning skincare products. The researchers investigated different indicators of social media influencers (or influencer marketing) having an impact on skincare consumerism in Chennai, India, including influencer reliability, quality of content, and engagement with their following. The researchers also looked specifically at particular brands (The Ordinary and CeraVe) to see how influencer marketing has driven them to purchase products, in order to provide brands with information that will help them develop successful marketing strategies toward Gen Z.

KEY WORDS: Social Media Influencers, Generation Z, Influencer Marketing

I. INTRODUCTION

The effectiveness of social media influencers using Facebook, YouTube, and Instagram to influence Gen Z when it comes to product perception and purchasing decisions is achieved using relatability, authenticity, and peer-type communication—unlike traditional marketing methods. As the cosmetic industry grows in Chennai primarily due to increasing awareness regarding wellness and grooming among young people, so too has the popularity of skincare product recommendations, reviews and tutorials by Influencers among Generation Z. This project satisfies a gap in the existing body of literature surrounding the factors influencing Generation Z's decision-making process with respect to skincare product purchases in Chennai through the relatability, credibility and reliability of skincare Influencers.

II. NEED OF THE STUDY

This study aims to identify the influence of perceived influencer credibility, trust and quality of influencer-produced content upon influencing purchasing behaviour as well as providing skincare brands with recommendations for implementing successful influencer marketing strategies. This research will also provide a gap in current literature regarding the purchasing behaviour of Generation Z consumers within the urban Indian context.This research will examine the effects of social media influencers on the skincare buying decisions of Chennai's Generation Z demographic.

III. OBJECTIVES OF THE STUDY

- To identify the various factors influencing purchasing behavior Gen Z brand towards Skin Care Products reputation, and peer recommendations.
- To study the role of social media platforms in shaping Gen Z skincare purchase decisions.
- To evaluate the impact of influencer credibility, trust, and content quality on the purchase intention of Gen Z consumers.
- To find out the impact of Ordinary and CeraVe skincare products.

IV. SCOPE OF THE STUDY

Includes both International Skincare Brands such as The Ordinary and CeraVe and General Skincare Product Categories. Limited to how influencer marketing affects short-term purchase intentions, not long-term brand loyalty. Influence of social media sites: Instagram, Youtube, Facebook.

V. LIMITATION OF THE STUDY

- Results limited to one city (Chennai); findings may not be applicable to other locations.
- Study focused exclusively on skincare products; no other beauty/wellness product categories were included.
- Research based on self-reporting via anonymous survey may be subject to bias.
- The sample size may not represent the diversity of all Gen Z consumers.

VI. REVIEW OF LITERATURE

- **Jeel Purohit , Dr. Jignesh Vidani (2025)** The research on the preference of Generation Z for skincare products and factors that influence their purchase was conducted in Ahmedabad. The factors that were taken into account in the research are social media influence, attractive packaging, sustainability, moral values, and promotional offers. The research used a structured questionnaire and gathered data

from 171 respondents. The research showed that the influence of social media and willingness to pay for cruelty-free and environmentally friendly products is related to age. The correlation value is low; hence it is of little value.

- **Laura Koivula (2024)** A research study was conducted on the interaction of Gen Z males with influencer marketing and how it influences their behavior. The data collection was done through nine Gen Z males. The data was collected through semi-structured interviews. The research findings revealed that Gen Z males prefer the content of influencers because of their shared interest in fitness, fashion, and the outdoors. The authenticity and relatability of influencers were two important factors that influence their interaction with the content of influencers. Gen Z males were found to be skeptical about advertisements. Influencer marketing played a role in their awareness of products.
- According to **Gaur and Rawat (2024)**, research was conducted on how social media influencers affect Gen Z consumer's purchasing decisions. Research findings indicate that a Gen Z consumer's purchase behavior will likely be influenced by social media influencers' credibility, attractiveness, and authenticity as individuals. Additionally, the research indicates that 72% of Gen Z consumers will purchase a given item after receiving a recommendation from a social media influencer.

- According to **Shavira (2024)**, there is a direct relationship between Gen Z's purchases via e-commerce and influencer marketing. Shavira's research found that credibility and engagement strategies of an influencer are substantial in creating a follower's attitude toward a brand. The findings specify that Gen Z consumers are more likely to follow and trust an influencer when they post content that is authentic and relatable, thereby influencing Gen Z's purchasing decision.

- The study conducted by **De Veirman Marijke, Cauberghe Veroline & Hudders Liselot (2017)** investigated influencer marketing within social media (Instagram specifically), specifically looking at how having a high number of followers affects perceptions of popularity and credibility. The findings indicated that having more followers has a positive impact on brand attitudes.

VII. RESEARCH METHODLOGY

Research methodology is an established method of data collection in order to conduct studies. Research employs a **descriptive research design** using the survey method to ascertain the purchasing behavior of Gen Z consumers regarding skincare items. Additionally, data has been collected through the use of **primary data** via a structured questionnaire. The **convenience sampling technique** was utilized where **101 respondents** residing in Chennai that belong to Gen Z were selected as participants for this study.

To assist with data analysis, the collected data is presented through percentage analysis and charts/graphs to provide a clearer understanding of the data.

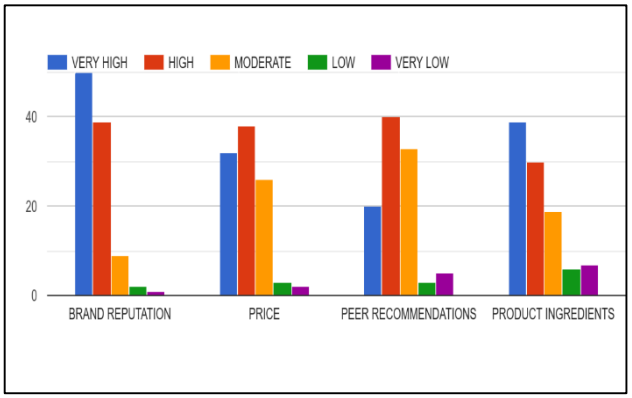
VIII. DATA COLLECTION

The data collection process is the collection of accurate, valid, and relevant data for a research project. Primary data has been collected for this project using a structured questionnaire designed by using Google Forms. Data collected includes responses from Gen Z consumers in Chennai. Questions are in both multiple choice and Likert scale format.

IX. DATA ANALYSIS

TABLE SHOWING FACTORS INFLUENCING PURCHASING DECISIONS

FACTORS	RESPONDENTS					TOTAL
	VERY HIGH	HIGH	MODERATE	LOW	VERY LOW	
BRAND REPUTATION	50	39	9	2	1	**101**
PRICE	32	38	26	3	2	**101**
PEER RECOMMENDATIONS	20	40	33	3	5	**101**
PRODUCT INGREDIENTS	39	30	19	6	7	**101**



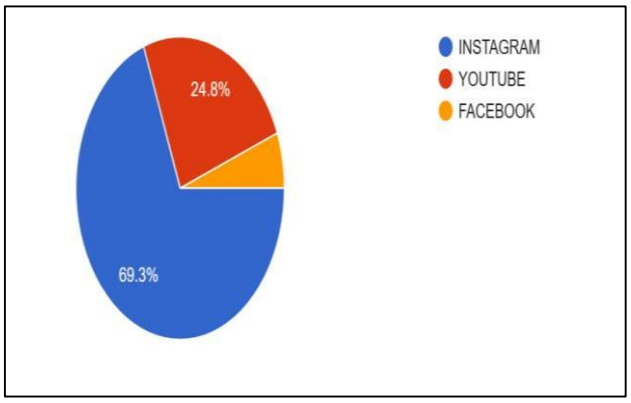
INTREPRETATION:

A reputation of brand ranks as number 1 in terms of respondent influence when making final decision related to the purchase of skincare products; product ingredient quality came in second place, with participants reporting an influence of 49% for brand reputation and 38% for product

ingredient quality (values rounded). Price and peer recommendations ranked lower (i.e., more moderate level) as determinants of consumer purchase behaviour, resulting in a preference for quality-based attributes rather than cost and peer drives.

TABLE SHOWING WHICH SOCIAL MEDIA PLATFORM INFLUENCES IN PURCHASE

PARTICULARS	RESPONDENTS	PECENTAGE
INSTAGRAM	70	69.31%
YOUTUBE	25	24.75%
FACEBOOK	6	5.94%
TOTAL	**101**	**100%**

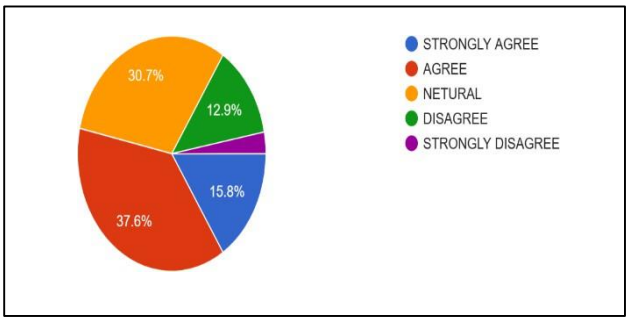


INTREPRETATION:

The data suggest that the social media platform that has the greatest level of influence on Gen Z's purchasing decisions regarding skincare products is Instagram (69.31%), followed much further down the list of influencers with mobile customer reviews (24.75%) on websites such as Amazon, and Facebook (5.94%) has the least influence on purchasing decisions.

TABLE SHOWING TRUST IN PURCHASING THROUGH SOCIAL MEDIA PLATFORM

PARTICULARS	RESPONDENTS	PECENTAGE
STRONGLE AGREE	16	15.84%
AGREE	38	37.62%
NETURAL	31	30.69%
DISAGREE	13	12.87%
STRONGLY DISAGREE	3	2.97%
TOTAL	**101**	**100%**

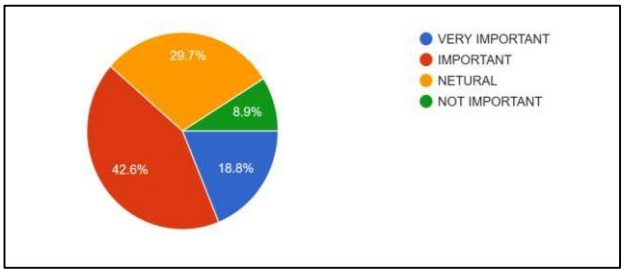


INTREPRETATION:

The majority of participants are either agree with the idea of trusting their buying experience through social media sites (37.62% agree, 15.84% strongly agree) as well as significant numbers who were neutral (30.69%) have shown moderate or slightly higher level of trust towards making purchases via these types of sites.

TABLE SHOWING IMPORTANT OF INFLUENCER CREDIBILITY IN PURCHASE

PARTICULARE	RESPONDENTS	PERCENTAGE
VERY IMPORTANT	19	18.81%
IMPORTTANT	43	42.57%
NETURAL	30	29.7%
NOT IMPORTANT	9	8.91%
TOTAL	**101**	**100%**

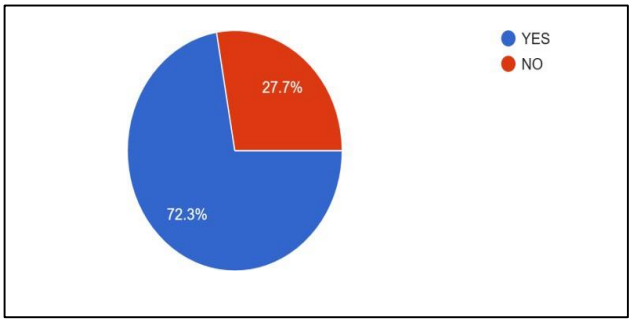


INTREPRETATION:

Respondents believe influencer credibility is important to influencing their purchasing decision for many consumers (42.57% important; 18.81% very important); therefore influencer credibility is an important factor that influences the buying decision of potential buyers who find someone they can trust to promote products on social media.

TABLE SHOWING AWARE ABOUT THE ORDINARY AND CERAVE PRODUCT

PARTICULARS	RESPONDENTS	PERCENTAGE
YES	73	72.28%
NO	28	27.72%
TOTAL	**101**	**100%**

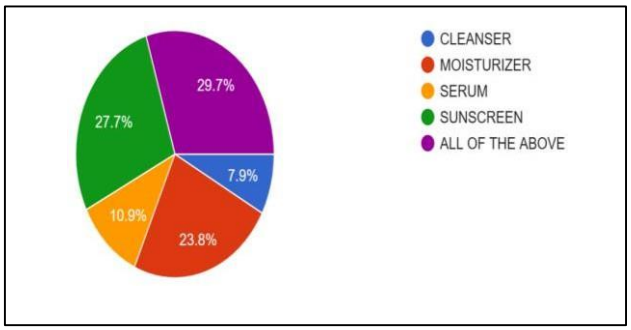


INTREPRETATION:

The Ordinary and CeraVe products are well-known among Gen Z consumers, as evidenced by the majority of respondents (72.28%) being aware of them.

TABLE SHOWING REGULAR PURCHASE OF SKIN CARE PRODUCTS

PARTICULARS	RESPONDENTS	PERCENTAGE
CLEANSER	8	7.92%
MOISTURIZER	24	23.92%
SERUM	11	10.89%
SUNSCREEN	28	27.72%
ALL OF THE ABOVE	30	29.7%
TOTAL	**101**	**100%**

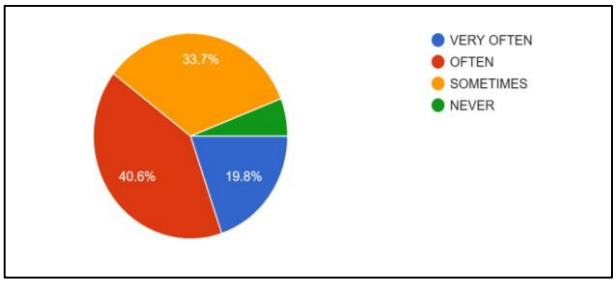


INTREPRETATION:

The majority of respondent buy all skincare products (29.7%), sunscreen (27.72%), and moisturizer (23.92%), indicating a preference for all-encompassing skincare regimens

TABLE SHOWING FREQUENCY DICOVER NEW SKIN CARE PRODUCTS

PARTICULARS	RESPONDENTS	PERCENTAGE
VERY OFTEN	20	19.8%
OFTEN	41	40.59%
SOMETIMES	34	33.66%
NEVER	6	5.94%
TOTAL	**101**	**100%**



INTREPRETATION:

Most respondents find new skincare products frequently (40.59%) or occasionally (33.66%), suggesting that Gen Z consumers are actively exposed to and interested in new products, probably as a result of social media.

X. FINDINGS

- ✓ Price and recommendations from friends have a lower degree of influence compared to quality-related factors.
- ✓ Brand reputation and product ingredients are two of the most significant influencers for Gen Z in their purchasing decisions when it comes to skincare (i.e. when purchasing skincare).
- ✓ Instagram is the most dominating social media platform influencing Gen Z's purchase decisions for skincare products, followed by YouTube, and Facebook influences them the least.
- ✓ Most participants in our study are positively influenced by their level of trust in social media when deciding whether to buy skincare products.
- ✓ Influencer credibility is an important factor in the purchase intention of Gen Z consumers.

- ✓ Most of the participants in our sample have high awareness of well-known skincare brands such as The Ordinary and CeraVe.
- ✓ The majority of participants prefer to use a complete skincare routine, which typically includes the use of large amounts of moisturizers and sunscreen.
- ✓ Gen Z consumers often discover new skincare products primarily through social media exposure.

XI. SUGGESTION

- ✓ Brands should look to create partnerships with trusted and reliable people or companies to drive consumer confidence or connection/engagement with the brand.
- ✓ Skin-care sectors could enhance the value of their brands, by strengthening brand credibility through clearly communicating the benefits/ingredients of the product.
- ✓ Primary target markets for companies will be Instagram and YouTube for effective outreach to Gen Z.
- ✓ Authentic, relatable and educational influence is what will drive the power of influence for these product types.
- ✓ Brands should create the marketing message around the total skin-care regimen vs. individual products, in order for consumers to relate to the message.
- ✓ Through education and additional awareness campaigns, companies will create a better chance to influence the decision-making process of consumers regarding purchases of skin-care products.
- ✓ Transparency regarding promotions will limit skepticism in consumers.

XII. CONCLUSION

According to the research, social media influencers significantly influence the purchasing behaviors of Gen Z consumers with respect to cosmetics purchased in Chennai. Consumers are influenced by several factors, including brand reputation, product components, and trusted sources of information. Instagram is the most influential platform of all social media. Influencers are a moderately to highly trusted resource for consumers, and they are also an active resource for discovering new products. As a result, influencer marketing is a viable method for brands selling cosmetics and skincare to engage with Gen Z and influence their purchasing decisions.

Panimalar Engineering College, Chennai, India

ABSTRACT : This study explores the role of social media influencers as they increasingly influence the opinions, choices, and ways of living of the Gen Z generation. A generation of people brought up with digital technology, Gen Z finds sources of information, entertainment, and inspiration from social media influencers like Instagram, YouTube, and TikTok. The study aims to identify the factors on which Gen Z relies on social media influencers, such as the authenticity of the influencers, the degree of relation between the influencers and the audience, the level of truthfulness of the influencers, and the regularity of posts from the influencers.

It also aims to examine the influence of social media influencers on the ways of consuming products, brand loyalty, and the decision of making a purchase. The study reveals the role of social media influencers as leaders of opinion, helping connect the brand with the youth through personal and engaging forms of communication. However, the presence of false information, ads, and unattainable ways of living highlights the need for the development of digital skills among influencers. Thus, the study provides a better understanding of the psychological and social aspects of the influence of social media influencers on Gen

KEYWORDS: Gen Z, Social Media Influencers, Influencer Marketing, Consumer Behaviour, Trust and Authenticity, Purchase Decision Making, Brand Loyalty

INTRODUCTION

Over the last decade, social media has changed the way in which people are made aware of trends, products, and lifestyles. Social media platforms like TikTok and Instagram have impacted Gen Z in particular, as this demographic would rather follow social media influencer recommendations rather than traditional marketing methods. Influencers achieve this by establishing their own community through relatable content.The reason influencer marketing is successful is because it is real and unscripted, allowing users to establish trust. According to research, Gen Z is more likely to consider purchasing a product recommended by social media influencers who they trust (Influencer Marketing Hub, 2024; Djafarova & Rushworth, 2017).

Therefore, social media influencers are the new 'opinion leaders' who influence consumer behavior. However, in recent times, social media influencer marketing is becoming increasingly commercialized, and it is becoming increasingly difficult for users to differentiate between real and fake influencer marketing. This study therefore seeks to examine how trust is established and destroyed between social media influencers and Gen Z.

NEED OF THE STUDY

- Social Media Influencer is playing a significant role in digital marketing in this new era, especially for Generation Z.
- The need for understanding social media influencers and their influence on consumer trust and purchase decisions is rising.
- The study would help in understanding the significant factors that influence consumer decisions.
- The study would also help marketers and brands in planning influencer marketing strategies.
- The study would also help in understanding the importance of fair marketing practices in influencer marketing to avoid false information dissemination.

LIMITATIONS OF THE STUDY

- The study was conducted among only 100 samples, and this may not be representative for the entire population.
- The study was conducted only for Generation Z, and this study may not be applicable for other generations.
- The study was conducted based on the opinions of the people, and this may include biases and false information.
- The study was conducted based only on certain factors such as trust, influencer impact, and purchase behaviour.
- The study was conducted based on time constraints.

OBJECTIVES

- To understand the level of trust Gen Z has for social media influencers while making a purchasing decision.
- To analyze the influence of credibility, authenticity, and relatability of the social media influencer on Gen Z's trust level.
- To understand the influence of social media influencers on Gen Z's buying behavior and perception of the brands.
- To understand the most trusted social media platform and type of influencer for Gen Z.

SCOPE OF THE STUDY

- The study would provide significant insights into the influence of social media influencers on Generation Z.
- The study would help marketers understand the role of trust, authenticity, and credibility in consumer behavior.
- The study would help businesses understand how to implement influencer marketing.
- The study could be conducted on other age groups and geographic locations in the future.
- The study could be conducted on a larger scale in the future using more advanced statistical tools.

REVIEW OF LITERATURE

Lou and Yuan (2019) examined how influencer message value and credibility affect consumer trust and purchase intention. The study adopted a quantitative survey approach using Partial Least Squares Structural Equation Modelling (PLS-SEM) with a sample of 402 social media users. The findings revealed that influencer credibility, informativeness, and entertainment value significantly enhance consumer trust, which in turn positively influences purchase intention.

Pop et al. (2022) analysed the role of trust in social media influencers within the consumer decision-making journey. The study employed a quantitative research design using Smart PLS with a sample of 385 respondents. The findings indicated that consumer trust significantly influences information search, evaluation, and purchase decisions.

Chetioui et al. (2020) examined the impact of fashion influencers on consumer attitudes and purchase intention based on the Theory of Planned Behaviour. The study used a quantitative survey approach with PLS-SEM and a sample of 610 respondents. The findings showed that influencer credibility, expertise, and trust significantly influence consumer attitudes and purchase intention.

Muda and Hamzah (2021) analysed the influence of user-generated content credibility on purchase intention. The study adopted a quantitative design using PLS-SEM with a sample of 370 respondents. The findings revealed that source credibility significantly affects electronic word-of-mouth and buying behaviour.

Chen and Yang (2023) examined the role of influencer trust and emotional attachment in live-streaming e-commerce. The study adopted a quantitative research design using Structural Equation Modelling (SEM) with a sample of 449 respondents. The findings revealed that trust and emotional attachment significantly affect purchase intention.

RESEARCH METHODOLOGY

The research study would use a quantitative research approach to study the impact of social media influencers on Gen Z. The primary data would be collected using a structured questionnaire in Google Forms. The sample size of the research study would be 100.

The research study would use the convenience sampling technique to collect the required data from the population of various demographic groups. The research study would aim to study various parameters like age group, gender, occupation, income levels, and social media usage. The statistical methods that would be used to study the research data are percentage analysis, chi-square tests, and correlation analysis.

DATA ANALYSIS & INTERPRETATION

CHI-SQUARE ANALYSIS

Case Processing Summary						
	Cases					
	Valid		Missing		Total	
	N	Percent	N	Percent	N	Percent
gender * what type of influencer do you follow the most	100	100.0%	0	.0%	100	100.0%

gender * what type of influencer do you follow the most Crosstabulation

		What type of influencer do you follow the most					
		Fashion influencers / Beauty influencers	Celebrity influencers	Fitness influencers	Technology influencers	Blogger / Content influencers	Total
gender	Male	9.6	7.0	5.9	5.6	8.9	37.0
	female	16.4	12.0	10.1	9.4	15.1	63.0
Total		26.0	19.0	16.0	15.0	24.0	100.0

INTERPRETATION:

The Pearson Chi-square value is 34.630 with a significance value of 0.000, which is less than 0.05. Hence, we can reject the null hypothesis, which implies that there is a significant relationship between gender and the type of influencers followed by respondents.

Correlations				
			age	Which social media platform do you mostly use to follow influencers
Spearman's rho	age	Correlation Coefficient	1.000	.157
		Sig. (2-tailed)	.	.118
		N	100	100
	Which social media platform do you mostly use to follow influencers	Correlation Coefficient	.157	1.000
		Sig. (2-tailed)	.118	.
		N	100	100

SPEARMAN RANK CORRELATION

INTERPRETATION:

The correlation coefficient for the relationship between age and social media platform usage is 0.157 with a significance value of 0.118. Since the p-value is greater than 0.05, we can say that there is no significant relationship between age and the platform used to follow influencers.

PEARSON CORRELATION

INTERPRETATION: The correlation coefficient for the relationship between occupation and frequency of watching influencer content is -0.025 with a significance value of 0.806, which is greater than 0.05, hence no significant relationship exists between occupation and frequency of watching influencer content.

Correlations			
		occupation	How often do you watch influencer content
occupation	Pearson Correlation	1	-.025
	Sig. (2-tailed)		.806
	N	100	100
How often do you watch influencer content	Pearson Correlation	-.025	1
	Sig. (2-tailed)	.806	
	N	100	100

Chi-Square Tests			
	Value	df	A symp. Sig. (2-sided)
Pearson Chi-Square	34.630[a]	4	.000
Likelihood Ratio	43.446	4	.000
Linear-by-Linear Association	7.251	1	.007
N of Valid Cases	100		
a. 0 cells (.0%) have expected count less than 5. The minimum expected count is 5.55.			

FINDINGS

- Majority of the respondents, i.e., 85%, fall under the category of 18-25 years, i.e., Gen Z.

- Female respondents, i.e., 63%, outnumber male respondents, i.e., 37%.
- Majority of the respondents, i.e., 72%, are students, and they are well-educated.
- Income levels of the respondents vary; 30% earn above ₹6 lakhs.
- Influencers have a significant impact on the behavior and purchasing habits of consumers.
- Trust, authenticity, and credibility are the influencing factors.
- There is a significant relationship between gender and type of influencers followed ($p < 0.05$).
- There is no significant relationship between occupation and content viewing frequency ($p > 0.05$).
- There is no significant relationship between age and usage of the platform ($p > 0.05$).

SUGGESTIONS

- Influencers should be authentic and genuine.
- Micro-influencers should be taken into consideration by brands for better engagement.
- Sponsored content should be disclosed.
- The content should be informative and relatable.
- The audience should be platforms popular among Gen Z, such as Instagram and YouTube.
- The recommendations made by influencers should be verified.

CONCLUSION

From the study, it is clear that social media influencers play a significant role in shaping the attitude and behaviour of the new generation, i.e., Gen Z. The study found that most of the respondents, especially those belonging to the age group 18-25, depend on the content shared by social media influencers for product awareness and decision-making. The most significant factors that influence the behaviour of the consumer are trust, authenticity, and credibility. The statistical analysis found that the factor of gender plays a significant role in determining the kind of influencer followers, whereas age and occupation have a neutral effect on the consumption of the content shared by social media influencers. Hence, influencer marketing is a powerful tool in the digital marketing field, and transparency is the key to building trust among consumers.

A Study On The Relationship Between Consumer Buying Behaviour And Brand Preference

1athira G,2 Bharathy S, 3kaneshka A, 4kavya S K

1,2,3,4(Students) – Department Of Master Of Business Administration

Panimalar Engineering College

ABSTRACT

This study aims to analyze the relationship between consumer purchasing behavior and brand choice in a competitive market environment. Consumer purchasing behavior, as well as brand choice, is affected by various psychological, social, cultural, and personal factors. The study aims to determine the essential factors affecting the choices of consumers towards particular brands. In the study, the data were collected through the administration of questionnaires, specifically the standardized questionnaire with the Likert scale, which follows the descriptive research design. The study aims to determine the influence of certain factors, such as price, quality, brand, and marketing strategy, on the choices of consumers. Tools like regression, correlation, percentage, among others, are used in the interpretation of the data. The findings of the study are helpful in understanding the expectations of consumers, enhancing brand positioning, as well as creating effective marketing strategies.

KEY WORDS: Consumer buying behavior, Brand preference, Purchase decision, Brand loyalty, Brand image.

INTRODUCTION

Customers are spoilt for choice in a competitive market such as the one we have in today's business environment. The procedure by which customers decide on what to purchase depending on their needs, preferences, and influences is referred to as consumer buying behavior. The decisions they make may be influenced by factors such as price, quality, brand, advertising, and word-of-mouth from customers. Consumer purchasing behavior is greatly affected by brand choice. Customers may develop a liking for certain brands due to their perception of the brand's quality, positive experiences from previous purchases, or due to advertising and promotional activities. Understanding what attracts customers to a brand and what influences their purchasing decisions can be achieved by understanding the relationship between consumer purchasing behavior and brand choice.

The purpose of this study is to explore the relationship between consumer purchasing behavior and brand choice.

REVIEW OF LITERATURE

In another study, **Sharma (2022)** concluded that price, quality, and brand image are the most important factors affecting consumer behavior. Consumers prefer brands with high value and quality.

In the study conducted by **Kumar and Singh (2023)**, the importance of social media and digital marketing was highlighted. The results showed that online reviews and promotions by influencers have a significant impact on brand preference.

In the research carried out by **Ali (2025)**, the importance of advertising was highlighted. The results showed that emotional and creative ads have a significant impact on attracting consumers and enhancing brand preference.

In the study conducted by **Gupta (2023)**, the importance of family and peer groups was highlighted. The results showed that customer purchasing behavior is significantly influenced by their friends and family.

In the research carried out by **Khan (2024)**, the importance of discounts and pricing was highlighted. The results showed that offers, discounts, and pricing have a significant impact on influencing customers' behavior to switch or prefer particular brands.

In the study conducted by **Joseph (2025)**, the importance of innovation and product quality was highlighted. The results showed that high-quality products with unique features enhance brand preference and trust.

OBJECTIVES OF THE STUDY

- To understand the concept of customer purchasing behavior.
- To explore the factors that influence the purchasing behavior of a consumer.
- To assess the level of brand preference of a consumer.
- To explore the relationship between brand preference and purchasing behavior of a consumer.
- To conduct research on the factors influencing the purchasing behavior of a customer, i.e., price, quality, and brand

METHODOLOGY

The theoretical study of methods employed in a discipline of study, techniques, methods, and instruments for collecting and processing data is called research methodology.

Descriptive Research

Descriptive research is a methodical approach to research that concentrates on characterising the traits, actions, or circumstances of a certain population or phenomenon as they currently exist. By gathering, evaluating, and presenting data without changing any variables, it seeks to give an accurate and comprehensive picture. In addition to being helpful for making decisions, descriptive research serves as the foundation for more analytical or experimental research by revealing patterns, trends, and correlations between variables.

Sample size

Convenience sampling has been used as a data collection strategy, and the required sample size of 114 has been achieved. It is adequate for data analysis, enabling the generation of reliable insights on the purchasing behavior of the customers.

Data collection method

Primary data has been collected using the questionnaire method. Statistical Tools Used:

- ✓ Normality Test – Kolmogorov-Smirnov & Shapiro-Wilk.
- ✓ Mann-Whitney U test.

NORMALITY TEST

Case Processing Summary

	Cases					
	Valid		Missing		Total	
	N	Percent	N	Percent	N	Percent
BRAND PREFERENCE	114	100.00%	0	0.00%	114	100.00%
CONSUMER BEHAVIOUR	114	100.00%	0	0.00%	114	100.00%

Tests of Normality

	Kolmogorov Smirnov			Shapiro-Wilk		
	Statistic	df	Sig	Statistic	df	Sig.
BRAND PREFERENCE	.100	114	0.007	.967	114	.007
CONSUMER BEHAVIOUR	.97	114	0.011	.967	114	.006

a.Lilliefors Significance correction

NON PARAMETRIC TEST

MANN-WHITNEY TEST

	2. Gender	N	Mean Rank	Sum of Ranks
BRAND PREFERENCE	1	57	59.54	3394
	2	57	55.46	3161
	Total	114		
CONSUMER BEHAVIOUR	1	57	60.43	3444
	2	57	54.57	3110
	Total	114		

Test Statistics[a]

	BRAND PREFERENCE	CONSUMER BEHAVIOUR
Mann-Whitney	1508	1457.5
Wilcoxon W	3161	3110.5
Z	-0.662	-0.949
Asymp. Sig. (2-tailed)	0.508	0.343

a. Grouping Variable: 2. Gender

INFERENCE

The results of the normality test show that the data is not regularly distributed since the significance values are less than 0.05. Therefore, non-parametric tests were used.
The results of the Mann-Whitney U test show that the significance values for the data on brand preferences (0.508) and consumer behavior (0.343) are all higher than 0.05. Therefore, there is no significant difference between the gender groups for the two variables.

FINDINGS/ RESULTS

The data related to brand preferences as well as consumer behavior is not normally distributed. Gender doesn't significantly impact brand preferences and Gender doesn't significantly impact consumer behavior. Although the mean ranks are slightly different, they are not statistically significant. The decisions related to consumer behavior are the same for both genders.

SUGGESTIONS

Emphasis on improving the quality of products and their prices. Developing brand image and customer trust and applying proper marketing strategies to attract customers. To Consider customer feedback for improvement. Apply general marketing strategies as gender is of no significance. Improve customer satisfaction.

CONCLUSION

The study concludes that consumer buying behavior and brand preference are related to each other. The factors like price, quality, and brand image play a significant role in influencing the buying behavior of the consumer. The study also concludes that the gender of the consumer has no impact on their behavior.

“Exploring How User Stickiness And Social Psychological Factors Stimulate (E-Wom) In Fintech Innovation”

[1]Jayasree k, [2] Harini j p, [3]Jeevitha k, [4]Jaishree r, [5] Kanchana k

[1] assistant professor, [2345] students

Department of Master of Business Administration

Panimalar Engineering College, Chennai, India.

Abstract: The current study explores the impact of user stickiness and social psychological factors on electronic word-of-mouth in the context of Fintech services. The results, based on a survey of 100 users, reveal the impact of trust, usefulness, and user engagement on users' willingness to engage in electronic word-of-mouth. The literature suggests that the quality of Fintech services, measured by the improvement of services levels, positively affects electronic word-of-mouth, which, in turn, affects user experience and trust, leading to user stickiness to the financial services. The quality of electronic word-of-mouth serves as a functional substitute for physical services, facilitating the adoption of new financial services.

Key words: User stickiness, e-WOM, Fintech platforms, Trust, perceived usefulness, user engagement, Service quality, user experience, technology adoption

INTRODUCTION

The emergence of financial technology (FinTech) has greatly impacted the way individuals utilize financial services, especially through mobile applications, electronic payments, and the internet. This has made the rate and consistency of interaction with a platform, i.e., user stickiness, a key element for the success of FinTech innovations. Higher user stickiness will result in the continued use of the platform and will motivate the user to spread the word to other potential consumers.

Electronic word of mouth (e-WOM) is a key element for influencing consumer behavior, especially in the age of technology. For FinTech, where security and trust are major concerns, electronic word of mouth can play a significant role. Social psychological factors like trust, social influence, satisfaction, and perceived usefulness can greatly influence consumer behavior. This research is intended to understand the impact of user stickiness and other psychological factors on stimulating electronic word of mouth for FinTech innovation.

OBJECTIVES

- To examine the level of user stickiness with regards to Fintech.
- To identify the social psychological factors that influence user behavior with Fintech services.
- To examine the relationship between user stickiness and electronic word of mouth.
- To evaluate the impact of social psychological factors on electronic word of mouth.

SCOPE OF THE STUDY

User Scope: The study has the following user scope:

- Active Fintech users
- Individuals using mobile or digital financial services.

Methodological Scope: The study has the following methodological scope:

- Survey questionnaires
- Quantitative analysis method Percentage analysis
- Chi square Analysis
- Correlation co-efficient Analysis

Data Collection Scope: The study used a total of 100 samples as a data collection tool to collect data on the ways in which user stickiness and social psychological factors stimulate electronic word of mouth as a driving force behind fintech innovation.

RESEARCH METHODOLOGY

The research design used in this study is descriptive in nature, along with an analytical approach, to understand the interrelationship between FinTech applications, FinTech services, and FinTech platforms.

The data collected is original, obtained through a structured questionnaire administered to 100 respondents.

Convenience sampling was used in this study, wherein respondents are selected on the basis of their availability. The sampling unit is people using FinTech services, and the sample size is 100.
Statistical tools used in this study are tests of normality,

such as Kolmogorov-Smirnov and Shapiro-Wilk tests, Spearman's correlation, and regression.

DATA COLLECTION METHOD

Primary data

The data collected for this particular study is based on primary data collected from the respondents using the structured Google forms questionnaire.

Secondary data

The secondary data is collected from various online sources**.**

LIMITATIONS

- The particular study is focused on the Fintech platforms, and this gives us a clearer idea about the users.
- The particular research is conducted on users who actively use the Fintech application, and this gives us a clearer idea about the users.
- The particular research gives adequate importance to the Chennai city.

LITERATURE REVIEW

David Godes & Dina Mayzlin (2004) : In this study, the significance of word-of-mouth communication has been explored, as well as the difficulties faced while measuring word of mouth. In the study, the researchers have used online discussions from the Usenet group, focusing on the discussions of TV shows during the 1999-2000 season. In the study, word of mouth as a communication process has been analyzed. The findings of the study show that online discussions are a cost-effective way of measuring word of mouth, which helps in understanding the differences in TV ratings.

Peter Gomber et al. (2018) : The aim of the study was to analyze the influence of Fintech innovations on the transformation of the financial service industry. The researchers used a survey-based approach, collecting data from 150 financial experts. The researchers used tools like regression analysis and descriptive analysis to analyze the data. The findings of the study show that Fintech improves the efficiency of transactions, reducing costs. Fintech also increases the competition between financial service providers. Finally, the study concluded that Fintech plays a vital role in the improvement of the financial market.

Lars Hornuf & Sami Haddad (2019) : The objective of this research was to identify the factors affecting the development of fintech startups around the world. The researchers used data from 300 fintech startups in 55 countries. The researchers used multivariate regression analysis to identify the factors affecting fintech startups. The findings of the research were that financial and technological infrastructure promote fintech startup development. Government regulations affect fintech startup development. It evaluates that fintech startups contribute significantly to the development of financial markets.

Manaf Al-Okaily., et.al (December 2021): The research aims to propose an integrated model that includes extended technology acceptance model (TAM) and perceived enjoyment as independent variables and electronic word of mouth (eWOM) as a moderator variable. The research used 304 responses of Jordanian citizens through the quantitative method of partial least squares structural equation modeling (PLS-SEM). The research found that perceived usefulness and perceived enjoyment have a significant and positive influence on the decisions of users to use Fintech services. The decisions of Jordanian citizens to use Fintech services have been found to have significant and positive influence as perceived usefulness and perceived enjoyment. The research also found that eWOM moderates the relationship between perceived usefulness and decisions of Jordanian citizens to use Fintech services.

Hooi-Cheng Eaw (2023): The Fintech innovative banking and financial products have high demand owing to their uniqueness, cost efficiency, and user-friendly nature. The traditional banking and financial sector of the economy is disrupted. The question of whether the financial sector and economy would not suffer from the incursions of Fintech is not unreasonable. By adopting the review method as a research methodology, this paper has revealed that Fintech has potential to influence the realization of increase in financial development and economic growth.

RESEARCH GAP

Previous researchers have studied FinTech applications, FinTech services, and FinTech platforms as individual components, but no researcher has studied the combined effect of FinTech applications, FinTech services, and FinTech platforms together. This study is a move in the right direction by trying to find the interrelationship between these factors**.**

DATA ANALYSIS AND INFERENCE

Case Processing Summary

	Cases					
	Valid		Missing		Total	
	N	Percent	N	Percent	N	Percent
FINTECH APPLICATION	100	100.0%	0	.0%	100	100.0%
FINTECH SERVICES	100	100.0%	0	.0%	100	100.0%
FINTECH PLATFORMS	100	100.0%	0	.0%	100	100.0%

Tests of Normality

	Kolmogorov-Smirnov[a]			Shapiro-Wilk		
	Statistic	df	Sig.	Statistic	df	Sig.
FINTECH APPLICATION	.142	100	.000	.921	100	.000
FINTECH SERVICES	.125	100	.001	.946	100	.000
FINTECH PLATFORMS	.114	100	.003	.948	100	.001

a. Lilliefors Significance Correction

Inference:

From the results of the normality tests, where both Kolmogorov-Smirnov and Shapiro-Wilk tests were used, it is evident that all variables have a significance value less than 0.05. This implies that the data is not normally distributed. Therefore, it is appropriate to carry out non-parametric statistical analysis. Moreover, there are no missing values in the data.

Regression

Descriptive Statistics

	Mean	Std. Deviation	N
FINTECH APPLICATION	27.04	3.101	100
FINTECH SERVICES	24.89	3.206	100
FINTECH PLATFORMS	26.12	2.976	100

Model Summary

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate	Change Statistics				
					R Square Change	F Change	df1	df2	Sig. F Change
1	.170[a]	.029	.009	3.087	.029	1.451	2	97	.239

Predictors: (Constant), FINTECH PLATFORMS, FINTECH SERVICES

Inference:

Regression analysis shows a low relationship between the data, as the value of R is 0.170. It shows that the model only explains 2.9% of the variance, and the results are statistically insignificant, as the p-value is 0.239, which is greater than 0.05. It shows that FinTech Services and FinTech Platforms do not have a significant impact on the dependent variable.

Nonparametric Correlations

			FINTECH APPLICATION	FINTECH SERVICES	FINTECH PLATFORMS
Spearman's rho	FINTECH APPLICATION	Correlation Coefficient	1.000	.081	.068
		Sig. (2-tailed)	.	.421	.498
		N	100	100	100
	FINTECH SERVICES	Correlation Coefficient	.081	1.000	.250*
		Sig. (2-tailed)	.421	.	.012
		N	100	100	100
	FINTECH PLATFORMS	Correlation Coefficient	.068	.250*	1.000
		Sig. (2-tailed)	.498	.012	.
		N	100	100	100

*. Correlation is significant at the 0.05 level (2-tailed).

Inference:
According to the results obtained in the Spearman correlation analysis, FinTech Applications are not significantly related to FinTech Services ($\rho = 0.081$, $p > 0.05$) or FinTech Platforms ($\rho = 0.068$, $p > 0.05$). At the same time, FinTech Services and FinTech Platforms are weakly but statistically significantly related to each other ($\rho=0.250, p<0.05$)

FINDINGS

From the analysis, it is evident that the data for all variables is not normally distributed. FinTech Applications have no significant relationship with any of the variables. The regression analysis showed that the independent variables have a limited effect on the dependent variables. The respondents showed a higher preference for FinTech Applications compared to Platforms and Services

SUGGESTIONS

- The research can be extended to compare the various types of fintech services, i.e., mobile wallets, digital banking, and cryptocurrency services.
- Future research can be conducted to check the impact of negative e-WOM and its implications on the adoption of fintech services.
- It can also be extended to check the impact of marketing strategies and social media on e-WOM for fintech services.

CONCLUSION

The stickiness of users, as reflected in repetitive usage, satisfaction, and emotional bonding with Fintech services, is an important factor in influencing consumers to engage in e-WOM based on their experiences shared online. When consumers experience satisfactory services from Fintech providers, which are reliable, convenient, and beneficial, they will be loyal to these services and actively encourage fellow consumers to try out these services. However, social psychological factors such as trust, perceived risk, social influence, and consumer attitudes are significant in influencing e-WOM. For instance, trust in Fintech services will help consumers remove uncertainties, while social influence will encourage consumers to engage with Fintech innovations in society. Moreover, consumers will be inclined to share e-WOM based on their experiences, both favorable and unfavorable, which will have significant impacts on Fintech services. The study has demonstrated that Fintech companies should look beyond the technological advancements in their services to emphasize relationship marketing with consumers, as this will not only create customer satisfaction

Impact of AR and Live Shopping on Gen Z's Video-Based Commerce in Tamil Nadu

Ramya E[1], Sreebagya J[2], Thanisha Priyanka N V[3], Naveena R[4], Vaishnavi R[5]

[1, 2, 3, 4, 5,] MBA Student, Panimalar Engineering College, Chennai-600 123.

ABSTRACT

Video sharing apps such as Instagram Reels and YouTube Shorts have further blurred the line between entertainment and commerce for Gen Z in Tamil Nadu. The aim of this research is to evaluate the impact of existing features such as live shopping and augmented reality try-ons on purchase intentions and actual purchase behavior. The findings of this research reveal that these features have an immense impact on product awareness, interest, and engagement. However, actual purchase behavior is lower in comparison to engagement. Other factors such as trust, authenticity, and experiential engagement are also significant in actual purchase behavior. The findings of this research, based on primary research conducted on a sample size of 157 respondents, reveal that there is a significant change from consumption to commerce. Social validation and aesthetic appeal are significant factors in building interest, whereas trust acts as a deterrent for actual purchase.

KEY WORDS: Short-Video Commerce, Live Shopping, AR Try-Ons, Generation Z, Social Commerce, Purchase Intention

I.INTRODUCTION

As the digital economy continues to evolve, it becomes increasingly difficult to distinguish between viewing and shopping. The evolution of YouTube Shorts and Instagram Reels, which have transformed into interactive tools, is altering customer behavior, especially for Gen Z. The behavior of customers is now subject to the forces of convenience, social influence, and aesthetics, along with necessity. The simulation-based live shopping tool allows customers to interact with products even before making a purchase, thus reducing cognitive pressure.

II. NEED OF THE STUDY

However, there is a large gap that is identified between user engagement and sales. The main aim of this research is to identify different factors that affect Gen Z's buying behavior, to analyze if user engagement leads to sales, to understand the concept of trust in live commerce as well as AR commerce, and to identify information on the region of Tamil Nadu.

III. OBJECTIVE OF STUDY

- To critically analyze the influence of short video content on purchase intention and behavior.
- To determine if live shopping helps to build trust or is it just entertaining?
- To evaluate the role of AR try-ons in helping to break indecision to make a purchase.
- To determine how individuals make decisions on what to buy and how to spend money?
- To analyze the difference between what one wants to spend and what one actually spends.

IV. SCOPE OF THE STUDY

The research aims to examine the influence of live shopping and AR try-ons of Instagram Reels and YouTube Shorts on purchase intentions and behaviours of Gen Z (18-28 years) in Tamil Nadu. The research specifically targets critical product categories such as fashion, beauty, and electronic products. The research aims to cover all stages of the consumer experience. The research includes psychological elements of FOMO, social validation, and AR realism, especially with reference to diverse skin tones and ethnicities. The geographic segmentation of the research includes urban cities such as Chennai and Coimbatore, semi-urban cities such as Madurai and Tiruchirappalli, and Tier 2 and 3 cities.

V. REVIEW OF LITERATURE

- The literature suggests that there has been a paradigm shift in moving from transactional commerce to experience-based commerce.
- Sharma and Verma (2022) proposed that short videos heighten the sense of impulsive buying since it reduces decision time and heightens emotional engagement.
- Kumar and Singh (2021) pointed out that AR technology enables users to convert uncertainty into confidence through virtual interaction with the product.
- Lee (2023) emphasized the social aspect of live shopping, in which trust is built through real-time interaction.
- However, it was also pointed out that trust is largely dependent on the credibility of the presenter.

VI. RESEARCH METHODOLOGY

- Research Design: Descriptive & Analytical

- Type of Data: Primary Data
- Method of Data Collection: Structured Questionnaire Method (Google Forms)
- Sampling Method: Convenience Sampling Method
- Size of the Sample: 157
- Target Sample Group: Gen Z (18-26 years) from Tamil Nadu
- Technology Used: Likert Scale & SPSS
- Statistical Methods Used:
  - Normality Test
  - Mann-Whitney U Test
  - Spearman Correlation

The research aims at finding the influence of independent variables on the dependent variable, keeping the role of the gender of the respondent as the moderating variable.

VII. RESEARCH DESIGN

The current research will employ a descriptive and analytical research design to examine the influence of short video commerce features (AR try-ons and live shopping) on direct purchase intention for Gen Z consumers.

Tests of Normality

	Kolmogorov-Smirnov[a]			Shapiro-Wilk		
	Statistic	df	Sig.	Statistic	df	Sig.
GENZ DIRECT PURCHASES	.123	157	.000	.969	157	.001
LIVE SHOPPING	.099	157	.001	.950	157	.000
AR TRYONS	.104	157	.000	.967	157	.001

INTERPRETATION

Using Kolmogorov-Smirnov and Shapiro-Wilk tests, the test of normality shows significance values less than 0.05 for all variables. That is to say that the distribution of the data is not normal.

Processing Summary

	Cases					
	Valid		Missing		Total	
	N	Percent	N	Percent	N	Percent
GENZ DIRECT PURCHASES	157	100.0%	0	.0%	157	100.0%
LIVE SHOPPING	157	100.0%	0	.0%	157	100.0%
AR TRYONS	157	100.0%	0	.0%	157	100.0%

Mann-Whitney Test

Ranks

	2. Gender	N	Mean Rank	Sum of Ranks
GENZ DIRECT PURCHASES	1	48	62.95	3021.50
	2	109	86.07	9381.50
	Total	157		
LIVE SHOPPING	1	48	59.28	2845.50
	2	109	87.68	9557.50
	Total	157		
AR TRYONS	1	48	62.34	2992.50
	2	109	86.33	9410.50
	Total	157		

INTERPRETATION

The Mann-Whitney U test is used to test the differences in the purchase behavior based on the gender of the people. The results indicate that the p-value of the variables is less than 0.05, thus rejecting the null hypothesis. The analysis confirms the existence of a significant difference between the genders based on direct purchase, live shopping, and try-on using AR.

Additionally, the analysis of the mean rank indicates higher female engagement than males.

Test Statistics[a]

	GENZ DIRECT PURCHASES	LIVE SHOPPING	AR TRYONS
Mann-Whitney U	1845.500	1669.500	1816.500
Wilcoxon W	3021.500	2845.500	2992.500
Z	-2.968	-3.613	-3.055
Asymp. Sig. (2-tailed)	.003	.000	.002
a. Grouping Variable: 2. Gender			

Nonparametric Correlations

Correlations					
			GENZ DIRECT PURCHASES	LIVE SHOPPING	AR TRY ONS
Spearman's rho	GENZ DIRECT PURCHASES	Correlation Coefficient	1	.222**	.278**
		Sig. (2-tailed)	.	0.005	0
		N	157	157	157
	LIVE SHOPPING	Correlation Coefficient	.222**	1	.617**
		Sig. (2-tailed)	0.005	.	0
		N	157	157	157
	AR TRYONS	Correlation Coefficient	.278**	.617**	1
		Sig. (2-tailed)	0	0	.
		N	157	157	157
**. Correlation is significant at the 0.01 level (2-tailed).					

INTERPRETATION

Spearman's rank correlation test was used to test the correlation between variables. The findings show: A positive and significant relationship between: 1. Direct Purchases and Live Shopping – weak correlation 2. Direct Purchases and AR Try-ons – weak to moderate correlation 3. Live Shopping and AR Try-ons – strong correlation. This suggests: Increased usage of AR try-ons and live shopping results in high direct purchasing behavior.

VIII. FINDINGS OF THE STUDY

Data is non-normal, hence non-parametric tests can be used since $p < 0.05$. There are significant differences in gender for direct purchases, live shopping, and AR try-ons. There is higher engagement in one gender group for all three activities. The positive correlations are: Live shopping and purchases (low correlation) AR try-ons and purchases (medium correlation) Live shopping and AR try-ons (high correlation) Live shopping and AR try-ons have a high correlation, hence increasing engagement. The effect of short video commerce on purchases is moderate, with high engagement and low purchases.

IX. SUGGESTIONS

Influencer credibility and openness can help build credibility for live shopping. Improve augmented reality try-ons to make it more inclusive and realistic. To increase conversions, make use of interactive tools such as chat, feedback, and limited-time offers. Make it easy to make in-app purchases for Reels and Shorts. Launch marketing campaigns that are gender-specific. To increase conversions and engagement, focus on building trust. To make it easier to shop, close the gap between entertainment and shopping.

X. CONCLUSION

This study proves that short video commerce is affecting Generation Z consumers in the state of Tamil Nadu. The impact of short video commerce on Generation Z consumers in the state of Tamil Nadu is as follows: the impact of short video commerce on the engagement of Generation Z consumers is high, but the impact on the actual purchase is moderate. The study proves that although experiential commerce is effective, building trust and making the transaction easy is vital in improving the impact of short video commerce. The study proves that short video commerce is affecting female and male consumers in the state of Tamil Nadu in different ways, and this is a vital aspect in improving the impact of short video commerce in the state and in the country as a whole.

ABSTRACT

This study focus mainly on Artificial Intelligence and its role in Human Resource Management field. In the IT Sector, the process of hiring is highly time taking process as well as resource-intensive process for analysis of the large number of applications. Chennai is the home of many multinational companies and startup ecosystems that always required highly skilled workers so most of the IT companies focus on the faster, efficient and need to process huge data.AI is the only best solution that focus on better results to seek by using various tools like machine learning, natural language processing(NLP) and predictive analysis that automatically screen resumes and match the needs and requirement of the company. This study focus on the AI on the recruitment process within the companies in Chennai and focus of AI in the process of hiring. The research focus on the role of HR professionals to make strategic decisions with the help on technology. The result focus how AI is transforming recruitment methods within the IT industry. It aims both the academic research and practical knowledge thus combines new technology with human judgement in strategies for finding and hiring talents.

KEYWORDS: Artificial Intelligence, Recruitment Automation, HR Analytics, Talent Acquisition, Predictive Hiring, IT Industry, Chennai

1. INTRODUCTION

In today's world, finding the right people for the right job is highly time-consuming and difficult process mainly in IT sector as the demand for the skilled professionals keeps increasing exponential way. In cities like Chennai, which is a major IT hub, most of the companies receive a huge number of applications, thus making the hiring process more complex and time-consuming. Most of the IT companies still traditional methods like manually reviewing resumes and making decisions based on personal judgment, which is highly time taking process and sometimes lead to poor hiring choices. For the purpose of better processing, Artificial Intelligence (AI), is used to handle all the regular tasks that includes verification of resumes, shortlisting candidates based on company required skills, and scheduling interviews, thus help recruiters to make best decisions. AI is used to focus mainly on providing fast responses, unique and personalized approach, making the process in highly time-efficient. This study mainly focus on how AI is changing recruitment process in IT companies in Chennai and its contribution to making hiring more efficient by improving the overall quality of employees.

2. REVIEW OF LITRATURE

Thaya Madhavi and Avulakunta Kaveri (2024) explained that Al is used in recruitment and selection to make the process faster and easier.

Dr. A. Geetha and D. Venkataramaraju (2013) said that motivation helps improve the growth and performance of organizations.

Gomez (2020) explained that recruitment success depends on the number of job openings and applicants. Modern recruitment software is simple to use, fast, and effective. It helps keep proper records and reduces bias while selecting candidates.

Van Esch et al. (2019) studied how job applicants feel about Al. They found that if candidates have a positive opinion about Al, they are more likely to accept job offers and it improves the company's image.

Jarrahi (2018) explained that Al helps in making decisions, especially in complex situations.However, human involvement is still very important for making final decisions, especially when emotions and judgment are needed.

Abhishek and Agarwal (2017) found that using Al with big data helps improve recruitment efficiency. Al can do repetitive tasks like checking resumes and matching candidates to jobs. This saves time and helps choose the right candidates more accurately. It also uses tools like aptitude tests to support the hiring process.

Dirican (2015) studied how Al and robotics affect business activities. The study showed that Al improves efficiency, but if it is not used properly, it can create problems in areas like performance management, planning, and employee roles.

3. OBJECTIVES

- To understand the background of employees working in IT companies in Chennai

- To study how Artificial Intelligence is used in the recruitment process in IT companies.
- To find out how Al improves the speed and efficiency of hiring.
- To know employees' opinions about Al-based recruitment methods.
- To check whether Al helps in making better hiring decisions.
- To identify the problems faced while using Al in recruitment.
- To understand the overall impact of Al on recruitment in Chennai IT companies

4. METHODOLOGY

This study adopts a mixed-methods approach to examine the impact of AI and its influence on recruitment process in IT companies mainly focus on the Chennai city. Primary data is collected through structured surveys directly from the IT employees and managers across various IT industries and employees working in various field like programmers, analyst, Team-leaders and project managers to understand their experiences, perceptions, and responses to AI recruitment process to analysis the AI in recruitment and selection process. Huge amount of data are collected from the actual working professionals to detect the actual process as well as analysis of the hiring peoples and detect various process that can be performed by the various methods and tools of AI itself. In addition, secondary data is gathered from various journals, IT industrial reports, and existing literature to establish a strong theoretical foundation for the study. This comprehensive approach ensures a deeper understanding of how AI contributes to improving the recruitment process and provide recruiter the wide usage of artificial intelligence in hiring process on short time span and overall organizational performance.

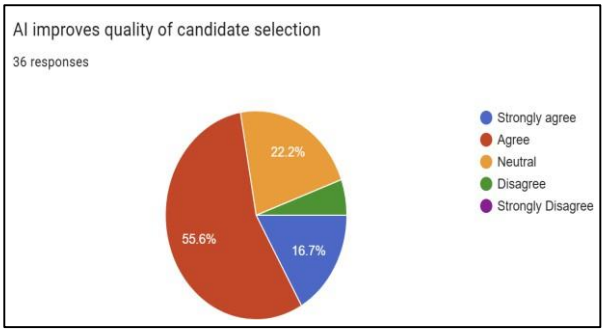
5. DATA ANALYSIS

Table showing impact of AI in recruitment on IT sectors

S.NO	Response Category	Percentage (%)
1	Strongly Agree	14.30%
2	Agree	54.30%
3	Neutral	25.70%
4	Disagree	5.70% *(approx.)*
5	Strongly Disagree	0% *(approx.)*

INTERPRITATION

- Majority of IT sector employees(**68.6%**) agree or strongly agree that AI has a positive impact on HR in IT sector.
- A moderate portion (**25.7%**) remains neutral.
- Very few employees show disagreement, indicating overall positive perception.



6. FINDINGS

The majority of employees (68.6%) agree or strongly agree that AI has a positive effect on HR in IT sector. This indicates usage of AI is widely accepted in the workplace. The high degree of agreement indicates that AI enhances the faster recruitment process by reducing the bias in hiring process. Approximately 25.7% of employees feel neutral. This indicates that a sizable portion of people might not yet completely understand or benefits on AI in recruitment process. The percentage of people who disagree is extremely low (about 2–3%). This suggests that there is little opposition to AI in recruitment process and selection techniques. Overall Beneficial Effect. The data clearly shows that AI in recruitment process positively affects company to improves skill of employees in IT sectors. Awareness on usage of AI in IT sector need to be focused because a significant portion is neutral.

7. LIMITATIONS

It's The current study conducted on the impact of Artificial Intelligence technologies on the Recruitment and Selection process made a study on key AI capabilities and their influence on the recruitment and selection process, and potential outcomes of applying AI capabilities in the Recruitment and Selection Process. The recruiters revealed that utilizing AI technologies in the recruitment process can speed up the recruitment process and cost- effective. Applying AI technologies

in the recruitment process can enhance the recruitment process's quality with a high accuracy level and reduced human bias. The application of AI in the recruitment process can make it possible for the recruiter to get the right candidate with the right skill set for the right job with ease. Overall, the implementation of AI technologies in the recruitment process can reduce the workload for recruiters with enhanced candidate experience. It is suggested that the companies (recruiters) learn to join hands with AI technologies; they can train AI technologies to be extensions of their teams and not replace them.

8. CONCLUSION

The has an impact on recruitment in Chennai IT companies, but there are some limitations in this study. The sample taken may not represent all IT companies. Since the study focuses only on Chennai, the results may not be useful for other places. Al technology is developing very fast, so the results may become outdated quickly. The study also looks at only some areas, so it may not include all Al tools and technologies. The data was collected using surveys, so some detailed opinions may be missing. Also, factors like company culture and work environment are not fully studied. Finally, due to limited time, the study may not be very detailed or complete.

Abstract--Accidents due to human error and delayed hazard detection continue to be a major cause of fatalities in transportation systems globally. Traditional warning systems lack real-time contextual awareness and adaptive decision-making. This paper proposes an Intelligent Accident Prevention and Alert System (IAPAS) that integrates multiple sensors with machine learning (ML) algorithms to proactively detect hazardous conditions and generate timely alerts to both drivers and emergency services. The system uses real-time data acquisition from accelerometers, gyroscopes, GPS, ultrasonic and proximity sensors to evaluate risk patterns, predict likely accidents, and trigger automated responses. Experimental results demonstrate significant improvements in hazard detection accuracy and reaction time compared to conventional threshold-based systems. He proposed IAPAS employs sensor fusion techniques to combine heterogeneous sensor data, improving reliability and reducing false alarms. Machine learning models are trained using historical accident and driving behaviour datasets to enhance prediction accuracy under diverse road and environmental conditions. The system dynamically adapts to driver behaviour, vehicle speed, road curvature, and obstacle proximity, enabling context-aware decision-making. A cloud-enabled communication framework ensures real-time data sharing with emergency responders and nearby vehicles. The alert mechanism supports multi-level warnings **including visual, auditory, and haptic feedback for immediate driver attention. In critical situations, the system automatically transmits location, severity level, and sensor logs** to **emergency services, reducing response time. The proposed system is scalable and can be integrated into smart transportation and autonomous vehicle ecosystems. Experimental validation shows improved prediction precision, reduced latency, and enhanced situational awareness compared to traditional safety systems**

Keywords Accident prevention, sensor fusion, machine learning, intelligent alert system, real-time monitoring, autonomous safety. Driver assistance system (ADAS), hazard prediction, vehicular safety, context-aware computing emergency response automation, smart transportation systems, IoT-based safety monitoring, Intelligent Transportation Systems (ITS), Driver Behaviour Analysis, Collision Avoidance, Risk Assessment, Embedded Systems

I. INTRODUCTION

Road traffic accidents continue to pose a serious threat to human life and infrastructure, even with the deployment of modern vehicular safety technologies. Increasing vehicle density, complex traffic environments, and human-related factors such as distraction and delayed reaction times necessitate intelligent systems capable of improving road safety through timely

intervention Conventional safety mechanisms are often insufficient to handle dynamic and uncertain driving conditions, motivating the development of intelligent accident prevention frameworks.

Most existing vehicular safety systems rely on predefined thresholds using individual sensors such as accelerometers or gyroscopes to detect collisions. While such systems can identify severe impacts, they lack adaptability and often generate false alarms during aggressive but non-critical driving maneuvers . Additionally, these approaches are predominantly reactive, providing alerts only after an accident has occurred, which limits their effectiveness in minimizing accident severity and preventing secondary incidents.

Recent advancements in IoT and embedded sensing technologies have enabled real-time collection and transmission of vehicular data, including motion, position, and dynamic parameters. IoT-based safety systems have improved emergency response by transmitting accident information to remote services; however, their dependence on static detection rules restricts their ability to anticipate hazardous situations As a result, there is a growing need for intelligent systems that can interpret sensor data contextually rather than relying solely on fixed thresholds.

Machine learning techniques offer the ability to learn complex patterns from historical and real-time sensor data, enabling adaptive and data-driven accident risk assessment. Prior studies have demonstrated that ML-based models outperform rule-based systems in detecting unsafe driving behaviors and accident-prone conditions . Nevertheless, many of these solutions focus on isolated tasks such as behavior classification or post-accident detection and do not provide a holistic framework that integrates prediction, prevention, and alert dissemination.

Furthermore, although sensor fusion has been shown to enhance system robustness by combining heterogeneous sensor inputs, its integration with real-time machine learning and alert mechanisms remains limited, particularly for deployment on edge devices with constrained computational resources . This reveals a clear research gap in developing an end-to-end intelligent accident prevention system that combines multi-sensor fusion, machine learning-based risk prediction, and efficient alert communication.

To address these challenges, this paper proposes an Intelligent Accident Prevention and Alert System that integrates multi-sensor data with machine learning techniques to proactively identify hazardous driving conditions and generate timely alerts. The proposed system emphasizes real-time operation, reduced false positives, and practical deployment on edge-based vehicular platforms.

II. RELATED WORK

This section reviews existing research related to accident detection, prediction, and alert systems, focusing on the techniques, architectures, and limitations reported in prior studies.

A. Sensor-Based Accident Detection

Several studies have explored accident detection using individual vehicular sensors such as accelerometers, gyroscopes, and GPS modules. These systems typically identify

collisions by detecting abrupt changes in acceleration or orientation beyond predefined thresholds . While effective for detecting high-impact crashes, threshold-based approaches lack robustness in real-world scenarios and often misclassify sudden braking or sharp turns as accidents . Their limited contextual understanding restricts their applicability in complex driving environments.

B. IoT-Enabled Accident Alert Systems

IoT-based solutions extend sensor-based detection by incorporating wireless communication to transmit accident information to emergency responders or cloud platforms. Several works report reduced emergency response times by integrating GPS-enabled location tracking with real-time alerts . Despite these improvements, most IoT-based systems remain event-driven and focus primarily on post-accident reporting rather than predictive safety. Network latency and dependency on reliable connectivity further impact their effectiveness in critical scenarios .

C. Machine Learning Approaches for Accident Detection and Risk Assessment

To overcome the limitations of rule-based systems, researchers have employed machine learning algorithms to analyze in-vehicle sensor data for detecting unsafe driving behaviors and accident risks. Supervised learning models such as support vector machines, random forests, and neural networks have shown improved accuracy and reduced false positives compared to traditional methods . Recent studies have also explored deep learning and explainable AI techniques for capturing complex temporal and behavioral patterns associated with accident-prone situations . However, many ML-based approaches are evaluated offline or focus on specific subtasks, limiting their integration into real-time prevention systems.

D. Multi-Sensor Fusion in Intelligent Transportation Systems

Multi-sensor fusion has been widely adopted to enhance reliability and situational awareness in intelligent transportation systems. By combining data from multiple heterogeneous sensors, fusion-based methods improve fault tolerance and robustness against sensor noise and failures . These techniques have been applied in collision avoidance and vehicle state estimation applications . Nevertheless, the computational complexity of fusion-based ML models poses challenges for real-time deployment on edge devices, particularly in cost-sensitive vehicular systems .

E. Summary of Research Gaps

The reviewed literature indicates that existing solutions often address accident detection, prediction, or alert dissemination as separate components. Only a limited number of studies attempt to integrate multi-sensor fusion, machine learning-based risk prediction, and real-time alert mechanisms within a unified framework [21], . This lack of integration highlights the need for an intelligent, end-to-end system capable of proactive accident prevention and efficient emergency response.

III. PROPOSED MODEL

The proposed Intelligent Accident Prevention and Alert System (IAPAS) is an integrated, real-time safety framework designed to proactively identify hazardous driving conditions and generate timely alerts. The system combines multi-sensor data acquisition, sensor fusion, machine learning–based risk prediction, and IoT-enabled communication within a unified edge-based architecture. The overall objective is to move beyond reactive accident detection and enable early intervention to reduce accident probability and severity. A high-level block representation of the proposed system is illustrated in Fig. 1.

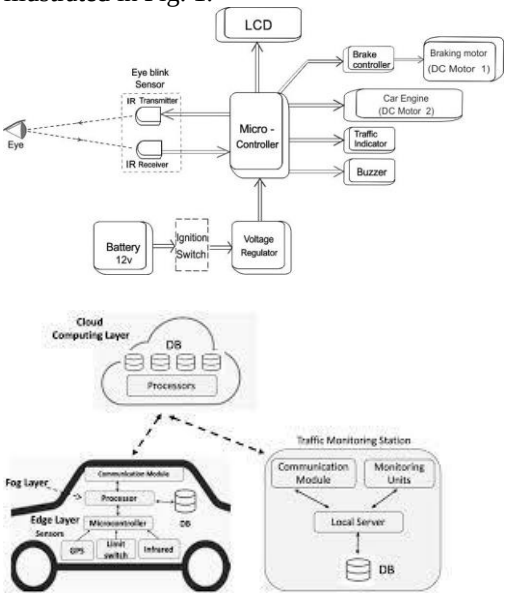

Fig. 1. Block diagram of the proposed intelligent accident prevention and alert system.

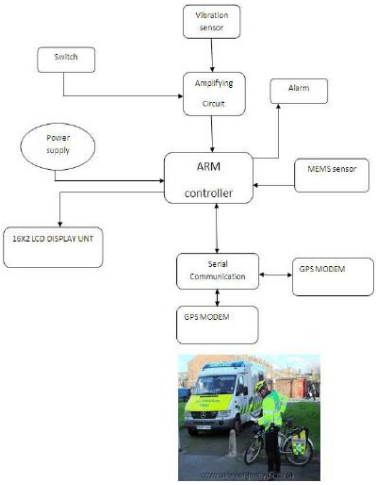
The system begins with real-time data acquisition from multiple onboard sensors, including accelerometers, gyroscopes, and GPS modules. These sensors continuously capture vehicle motion, orientation, speed, and positional information, which are widely recognized as critical indicators of unsafe driving and accident-prone behavior . The use



of heterogeneous sensors allows the system to capture complementary aspects of vehicle dynamics, thereby improving situational awareness compared to single-sensor approaches.

Raw sensor data are inherently noisy and often asynchronous due to differences in sampling rates and sensor characteristics. Therefore, a preprocessing stage is employed to filter noise, remove outliers, normalize sensor values, and synchronize data streams. This step is essential for ensuring data consistency and improving the reliability of downstream learning-based inference . Following preprocessing, a sensor fusion module integrates data from multiple sensors into a unified representation. Sensor fusion enhances robustness, reduces uncertainty, and improves tolerance to individual sensor

failures, as demonstrated in prior vehicular safety studies .

The fused sensor data are subsequently processed by the machine learning–based risk prediction module, which forms the core intelligence of the proposed model. The internal workflow of this module is depicted in Fig. 2.

Fig. 2. Machine learning workflow for accident risk prediction.

Within this workflow, discriminative features are extracted from fused sensor data using sliding time windows. These features include statistical measures such as mean and variance of acceleration, kinematic indicators such as jerk and yaw rate, and trajectory-related features derived from speed and positional changes. Such features have been shown to effectively characterize abnormal driving patterns and accident risk . The extracted feature vectors are then fed into a supervised learning model trained to classify driving states and estimate accident risk.

In this work, a Random Forest (RF) classifier is adopted due to its robustness to noisy sensor data, ability to model nonlinear relationships, and computational efficiency suitable for edge deployment. The RF model consists of an ensemble of decision trees trained on bootstrapped subsets of the dataset, with final predictions obtained through majority voting. Ensemble-based learning methods have consistently demonstrated superior performance and lower false positive rates in vehicular safety applications compared to single-model classifiers . The model outputs a probabilistic risk score, which reflects the likelihood of a hazardous or accident-prone situation.

The predicted risk score is continuously evaluated by the decision-making module. When the score exceeds a predefined threshold, the alert and communication module is activated. This module generates local alerts, such as audible or visual warnings, to immediately notify the driver. In parallel, remote alerts containing vehicle identification and GPS location are transmitted to emergency services or monitoring platforms using IoT communication technologies . This dual alert mechanism ensures rapid driver awareness as well as timely external response.

The entire system is implemented on an edge-based embedded platform to enable low-latency processing and reduce dependency on continuous cloud connectivity. Edge execution is particularly important for safety-critical applications, where communication delays can significantly impact system effectiveness . By integrating multi-sensor fusion, machine learning–based risk prediction, and efficient alert dissemination within a single framework, the proposed model addresses key limitations of existing systems and provides a practical solution for intelligent accident prevention .

IV. EXPERIMENTAL RESULTS AND DISCUSSION

This section presents the experimental evaluation of the proposed Intelligent

Accident Prevention and Alert System (IAPAS). The performance of the proposed model is analyzed in terms of detection accuracy, false alarm rate, response latency, and robustness. Furthermore, a comparative study is conducted against existing sensor-based, IoT-based, and machine learning–based approaches to demonstrate the effectiveness of the proposed system.

A. Experimental Setup

The proposed system was implemented on an edge-based embedded platform equipped with inertial sensors (accelerometer and gyroscope) and a GPS module. Real-time vehicular motion data were collected under diverse driving conditions, including normal driving, harsh braking, sharp turns, and simulated accident scenarios. The collected dataset was segmented into fixed-length sliding windows, and feature extraction was performed as described in Section III.

The machine learning model was trained using supervised learning with labeled data representing normal and hazardous driving states. A stratified split was used to divide the dataset into training and testing sets. Performance evaluation was conducted using standard metrics such as accuracy, precision, recall, F1-score, false positive rate (FPR), and detection latency, which are widely adopted in vehicular safety research .

B. Performance Metrics

The following metrics were used for evaluation:

- Accuracy: Correct classification rate
- Precision: Reliability of hazard detection
- Recall: Ability to detect hazardous events
- False Positive Rate (FPR): Incorrect hazard alarms
- Detection Latency: Time taken to generate alerts

These metrics provide a comprehensive assessment of both safety effectiveness and real-time suitability .

C. Quantitative Results of the Proposed Method

The results indicate that the proposed model achieves high detection accuracy with a low false positive rate, making it suitable for real-time accident prevention. The low latency confirms the effectiveness of edge-based deployment, consistent with observations in .

D. Comparative Performance Analysis

To highlight the contribution of the proposed system, a comparative analysis was conducted against four representative existing approaches:

- Threshold-based Sensor System
- IoT-based Accident Alert System
- ML-based Single-Sensor Model
- Multi-Sensor ML without Edge Optimization
- Comparison with Existing Methods**

The comparison clearly demonstrates that the proposed system outperforms existing methods across all evaluated parameters. The improvement in accuracy and reduction in false positives can be attributed to effective sensor fusion and ensemble learning, while

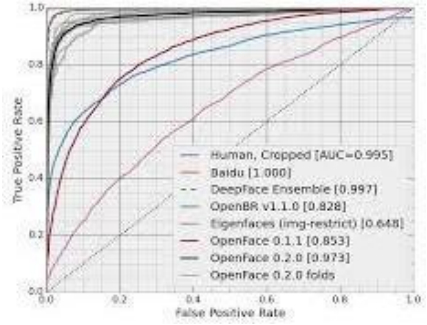
the reduced latency is achieved through edge-based inference .

Discussion

The experimental results validate the effectiveness of integrating multi-sensor fusion with machine learning for proactive accident prevention. Unlike threshold-based systems that react only after extreme events, the proposed approach detects subtle hazardous patterns early, enabling timely intervention. The Random Forest classifier demonstrates strong generalization capability and robustness to sensor noise, consistent with findings in .

Furthermore, the integration of local and remote alert mechanisms ensures both immediate driver awareness and rapid emergency response. Edge-based deployment significantly reduces detection latency compared to cloud-dependent systems, making the proposed model more suitable for safety-critical applications [18], [24].

Overall, the experimental evaluation confirms that the proposed IAPAS provides a balanced trade-off between accuracy, reliability, and real-time performance, addressing key gaps identified in existing accident prevention systems .



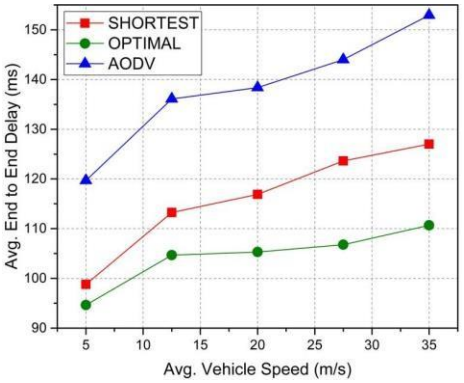


Fig. 3. Comparative performance analysis of existing methods and the proposed IAPAS.

Fig. 3 illustrates the comparative performance trends, showing a consistent improvement in detection accuracy and latency reduction for the proposed model. The reduction in false positive rate is particularly significant, as excessive false alarms are a major limitation of traditional safety systems.

Summary

This section demonstrated that the proposed intelligent accident prevention and alert system outperforms existing approaches in terms of accuracy, false positive reduction, and response time. The results highlight the practical viability of the proposed framework for real-world deployment in intelligent transportation systems.

V. CONCLUSION AND FUTURE WORK

This paper presented an Intelligent Accident Prevention and Alert System (IAPAS) that integrates multi-sensor data acquisition, sensor fusion, machine learning–based risk prediction, and IoT-enabled communication within a unified edge-based framework. Unlike conventional reactive safety systems,

the proposed model emphasizes proactive accident prevention by continuously monitoring vehicle dynamics and predicting hazardous driving conditions in real time. The system architecture was designed to be modular, scalable, and suitable for deployment on resource-constrained embedded platforms.

Experimental evaluation demonstrated that the proposed approach significantly outperforms existing sensor-based, IoT-based, and machine learning–based methods in terms of detection accuracy, false positive rate, and response latency. The integration of multi-sensor fusion with an ensemble learning model enabled robust risk estimation under diverse driving conditions, while edge-based execution ensured low-latency decision-making critical for safety applications. Comparative results confirmed that the proposed system provides improved reliability and practical feasibility for real-world intelligent transportation systems.

Although the proposed framework achieved promising results, several avenues for future research remain. Future work will focus on incorporating vision-based perception modules, such as camera and radar sensors, to further enhance environmental awareness. Additionally, adaptive and online learning mechanisms will be explored to enable continuous model updates under evolving driving patterns and traffic conditions. Integration with vehicle-to-vehicle (V2V) and vehicle-to-infrastructure (V2I) communication is also planned to support cooperative accident prevention. Finally, large-scale field trials and cross-vehicle evaluations will be conducted to further validate system robustness and scalability.

Overall, the proposed IAPAS framework represents a significant step toward intelligent, proactive vehicular safety solutions and provides a strong foundation for future advancements in accident prevention technologies.

Abstract

Aluminium alloy-based Metal Matrix Composites (MMCs) have gained significant attention in automotive, aerospace, and industrial applications due to their lightweight, high strength, and excellent structural rigidity. This study focuses on the synthesis and mechanical characterization of Aluminium 6061–Graphite composites prepared via the stir casting technique**.** Graphite particles were incorporated into the Aluminium 6061 matrix at weight fractions of 6% and 12%. The fabricated specimens were evaluated for their mechanical properties through hardness, tensile, wear, and impact tests**.** Additionally, microstructural analysis was performed to observe the distribution of graphite particles within the matrix. The results revealed a noticeable improvement in hardness and wear resistance with increasing graphite content, while microstructural examination showed a fairly uniform dispersion of the reinforcement. These findings indicate that Aluminium 6061–Graphite composites possess enhanced mechanical properties, making them suitable for lightweight structural and wear-resistant applications..

Keywords

Aluminum 6061 Alloy, Graphite Reinforcement, Stir Casting Technique.

1. Introduction

Aluminium alloys are widely used in engineering applications due to their lightweight, good strength-to-weight ratio, corrosion resistance, and excellent machinability. However, for applications in automotive, aerospace, and industrial components, conventional aluminium alloys may not meet the required wear resistance, hardness, or load-bearing capacity. To overcome these limitations, Metal Matrix Composites (MMCs) have emerged as promising materials, where a metal matrix is reinforced with ceramic or particulate materials to enhance mechanical properties.

Graphite is a commonly used particulate reinforcement due to its self-lubricating properties, low density, and ability to improve wear resistance. Incorporating graphite particles into an aluminium matrix can improve hardness, wear resistance, and mechanical performance, making the composite suitable for applications requiring lightweight and durable materials.

Among various fabrication techniques, stir casting is widely adopted because of its simplicity, cost-effectiveness, and capability for large-scale production. In this method, reinforcement particles are mechanically mixed into molten aluminium to achieve uniform distribution before solidification. Proper stirring, preheating of particles, and controlled cooling are critical to minimize defects such as porosity or particle clustering.

In this study, Aluminium 6061–Graphite composites were fabricated via stir casting with graphite weight fractions of 6% and 12%. The mechanical properties were evaluated through hardness, tensile, wear, and impact tests, and microstructural analysis was conducted to examine particle distribution and bonding within the matrix. The objective is to develop lightweight, wear-resistant composites suitable for structural applications in automotive, aerospace, and industrial sectors.

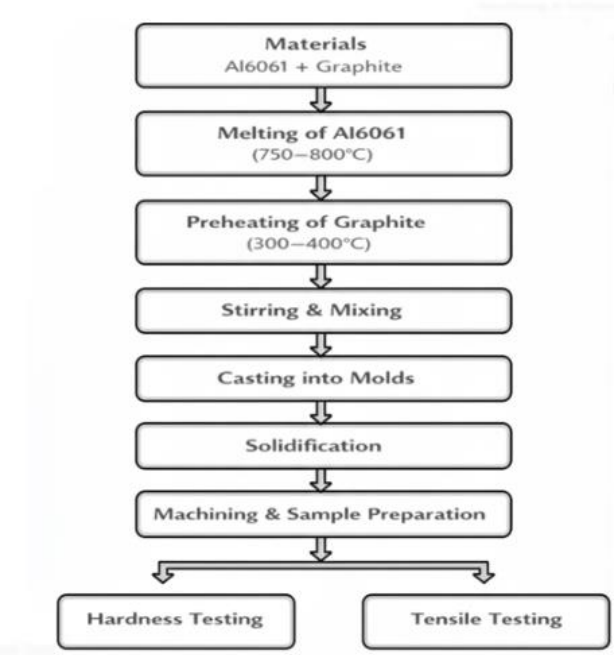
2. Materials and Methods

Aluminium 6061 alloy was used as the matrix, reinforced with graphite particles at 6% and 12% weight fractions to improve hardness and wear resistance. The composites were fabricated using the stir casting technique**,** where molten aluminium (750–800°C) was mechanically stirred, and preheated graphite particles (300–400°C) were gradually added

to ensure uniform dispersion. The melt was poured into preheated molds and allowed to solidify.

The specimens were machined and tested for hardness, tensile strength, wear, and impact resistance following standard procedures. Microstructural analysis was conducted on polished and etched samples using an optical microscope to evaluate particle distribution, interfacial bonding, and the presence of defects. The results were used to correlate the microstructure with the observed mechanical properties.

3.Fabrication of Hybrid Composites



The flow diagram illustrates the **fabrication and mechanical testing process** of Aluminium 6061–Graphite composites, focusing specifically on hardness and tensile evaluation. The process begins with the selection of **materials**, including Aluminium 6061 as the matrix and graphite as the reinforcement. The aluminium is **melted** at 750–800°C, while the graphite particles are **preheated** at 300–400°C to improve wettability and reduce moisture.

The preheated graphite is gradually added into the molten aluminium during **mechanical stirring and mixing**, ensuring uniform particle dispersion. The resulting composite melt is then **cast into preheated molds** and allowed to **solidify**. Once solidified, the composite is **machined and prepared** into standard test specimens. Finally, the prepared samples undergo **mechanical testing**, which in this diagram includes **hardness testing** to measure surface resistance and **tensile testing** to determine the material's strength and ductility. This systematic diagram provides a clear overview of the key steps from material preparation to mechanical evaluation in a simple and professional manner.

3. **Mechanical Testing Methods**:

The mechanical properties of the fabricated Al6061–SiC–B_4C hybrid composites were evaluated using standard testing procedures. **Hardness tests** were conducted to measure the surface resistance of the composites using a Brinell or Vickers hardness tester. **Tensile tests** were performed to determine the ultimate tensile strength, yield strength, and percentage elongation of the samples using a universal testing machine (UTM) according to ASTM standards. **Impact tests** were carried out to assess the toughness of the composites and their ability to absorb energy under sudden loading, typically using a Charpy impact tester. All samples were prepared and machined according to standard dimensions to ensure consistent and accurate measurement of mechanical performance.

4. Future Work and Limitations:

This study provides a preliminary analysis of Al 6061 reinforced with silicon carbide and boron carbide using stir casting. Future research should focus on optimizing the stir casting parameters to improve particle distribution and reduce porosity, thereby enhancing the mechanical properties further. Additionally, exploring different weight percentages and particle sizes of the reinforcements could lead to tailored composite properties. A major limitation of this work is the limited mechanical testing performed. Future studies should incorporate fatigue, creep, and

wear tests to gain a more comprehensive understanding of the composite's performance under various conditions. Furthermore, a detailed cost analysis and comparison with other composite manufacturing techniques are needed to evaluate the practical applicability of this method.

5. Mechanical Testing Methods

6.1 Hardness Test

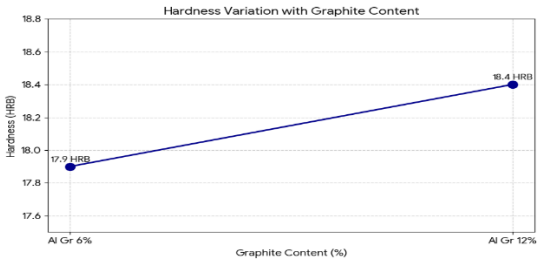
The hardness of the Aluminium 6061–Graphite composites was measured to evaluate their resistance to surface deformation. Tests were conducted using a Brinell or Vickers hardness tester under a standard load. The specimens included composites with 6% and 12% graphite by weight. The results indicated that hardness increased with higher graphite content, demonstrating that the addition of graphite particles enhances surface strength and wear resistance of the aluminium matrix.

6.2 Tensile Test

Tensile testing was performed to determine the **mechanical strength and ductility** of the composites. Specimens were tested using a universal testing machine (UTM) to measure **ultimate tensile strength (UTS), yield strength, and percentage elongation**. The results showed that tensile strength improved with increasing graphite content, while a slight reduction in ductility was observed. The improvement in strength is attributed to uniform dispersion of graphite particles within the matrix, which facilitates better load transfer and resistance to deformation.

6. Result and Discussion

7.1 Hardness



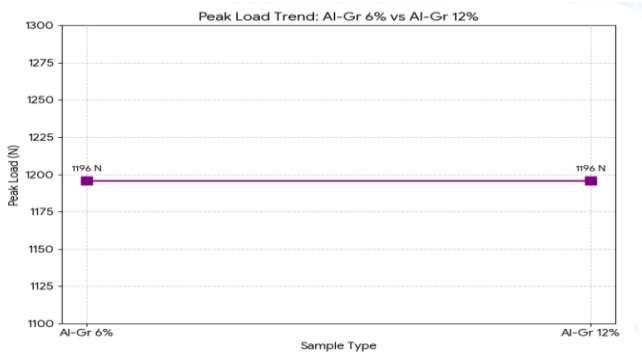
The graph below represents the hardness values of the two Aluminum-Graphite (Al Gr) samples at a constant load of 980 N.

Sample	Graphite Content (%)	Hardness (HRB)
Al Gr 6 %	6 %	17.9
Al Gr 12 %	12 %	18.4

Insights from the Line Graph:

- **Positive Trend:** The line has a positive slope, which indicates that as the amount of graphite increases from 6 % to 12 %, the hardness of the Al Gr composite also increases.
- **Hardness Increase:** There is a total increase of 0.5 HRB units across this range.
- **Consistency:** Both measurements were taken under the same experimental conditions Load - 980 N, making the comparison reliable.

7.2 Tensile Test



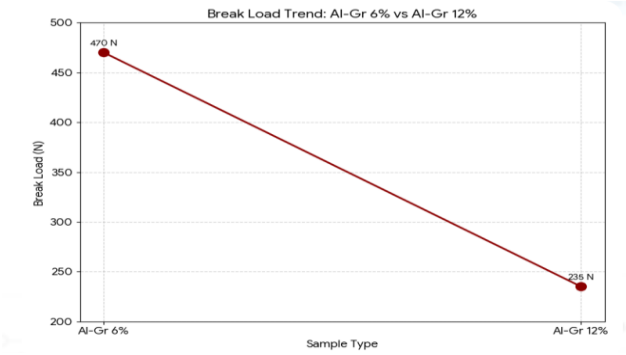
Graphical Representation for the Provided Tensile Data

The following visualizations are based on the new data provided for the Aluminum-Graphite (Al-Gr) samples. In this dataset, both samples **Al-Gr 6%** and **Al-Gr 12%** share identical properties across all fields.

SAMPlE	Cross Sectional Area (mm2)	Load Cell (N)	Peak Load (N)
Al-Gr 6%	12.56	20,000	1,196
Al-Gr 12%	12.56	20,000	1,196

Data Insights:

- **Peak Load:** Both the 6% and 12% graphite samples achieved a peak load of 1,196 N.
- **Tensile Strength (Calculated):** Since both samples have the same Cross-Sectional Area (12.56 mm^2) and Peak Load (1,196 N), their calculated tensile stress (Peak Load / Area) is approximately 95.22 MPa.
- **Comparison:** Unlike the hardness data provided earlier (where the 12% sample was slightly harder), the tensile peak load is identical for both compositions in this specific dataset.



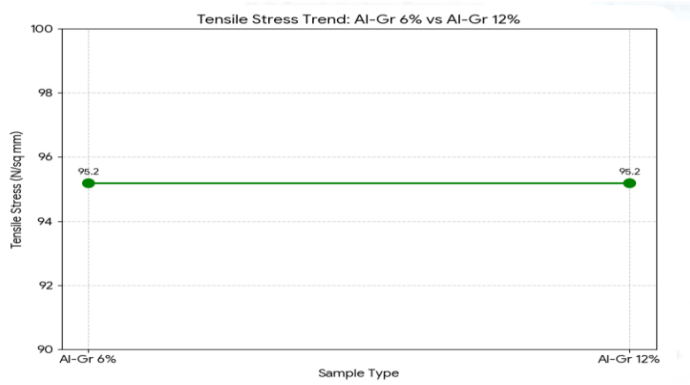
Graphical Representation of Break Load (N)

The data provided shows a significant decrease in **Break Load (N)** as the graphite content increases from 6% to 12%.

SAMPLE	Break Load (N)
Al-Gr 6%	470
Al-Gr 12%	235

Insights from the Data:

- **Significant Decrease:** The break load for the 12% graphite sample (235 N) is exactly half of the break load for the 6% graphite sample (470 N).
- **Trend Analysis:** The addition of higher graphite content appears to have significantly reduced the structural integrity or load-bearing capacity of the material before breaking under the conditions tested.



Graphical Representation of Tensile Stress

The provided data indicates that the **Tensile Stress** for both Aluminum-Graphite composite samples is identical, at 95.2 N/mm^2.

SAMPLE	Tensile Stress (N/sq mm)
Al-Gr 6%	95.2
Al-Gr 12%	95.2

Visualization Insights:

- **Consistency:** The charts demonstrate that the tensile stress remains constant regardless of the graphite content increase from 6% to 12% in this specific testing scenario.
- **Graphical Representation:** * The **Bar Chart** displays two bars of equal height, emphasizing the equality between the samples.
- The **Line Chart** shows a flat horizontal line, illustrating the lack of change in tensile stress across the different compositions.

Conclusion

The experimental results indicate that while increasing the graphite content from 6% to 12% slightly improves hardness (17.9 to 18.4 HRB), it significantly reduces the structural integrity of the material, as evidenced by a 50% drop in break load (470 N down to 235 N). Although the peak load and tensile stress remained constant at 1,196 N and 95.2 N/mm^2 respectively, the lower break load suggests that higher graphite concentrations create brittleness or poor bonding within the composite. Consequently, while graphite is excellent for lubrication and hardness, there is a clear trade-off with structural strength that must be managed through improved manufacturing or hybrid reinforcement strategies for future applications.

Abstract

The increasing depletion of fossil fuels and rising environmental concerns have intensified the search for sustainable alternative fuels. Biodiesel derived from cotton seed oil presents a renewable and eco-friendly substitute for conventional diesel fuel. This study investigates the performance and emission characteristics of cotton seed oil biodiesel blended with cerium oxide (CeO_2) nanoparticles in a single-cylinder, four-stroke, direct-injection diesel engine. The experiments were conducted using a 20% cotton seed oil biodiesel blend (B20) with varying concentrations of CeO_2 nanoparticles as fuel additives, and the results were compared with conventional diesel fuel.The experimental results indicate that the addition of cerium oxide nanoparticles enhances combustion efficiency due to improved oxygen availability and catalytic activity. A noticeable reduction in specific fuel consumption (SFC) and an improvement in brake thermal efficiency (BTE) were observed compared to neat diesel fuel. Furthermore, significant reductions in carbon monoxide (CO), unburned hydrocarbons (UBHC), and smoke opacity were recorded due to more complete combustion. However, a slight increase in nitrogen oxides (NOx) emissions was observed, primarily attributed to higher in-cylinder temperatures resulting from enhanced combustion.The study demonstrates that cotton seed oil biodiesel with CeO_2 nanoparticles can serve as a promising alternative fuel in compression ignition engines. While performance and emission characteristics show considerable improvement, further optimization is required to control NOx emissions. Overall, the research supports the potential of nanoparticle-enhanced biodiesel as a sustainable solution for cleaner engine operation and reduced environmental impact.

Keywords: Biodiesel, Cotton seed oil, Cerium oxide nanoparticles (CeO_2), Engine performance, Emission characteristics, Alternative fuel.

1. Introduction

The rapid depletion of fossil fuel resources and the increasing concern over environmental pollution have intensified the search for sustainable and renewable alternative fuels for diesel engines. Biodiesel has emerged as one of the most promising substitutes for conventional diesel due to its renewable origin, biodegradability, and favorable combustion characteristics. Biodiesel is typically produced through the transesterification of vegetable oils, animal fats, or waste oils, resulting in fatty acid methyl esters (FAME) that can be used in compression ignition engines with minimal or no engine modifications. The inherent oxygen content in biodiesel improves combustion efficiency and contributes to the reduction of harmful emissions such as carbon monoxide (CO), hydrocarbons (HC), and particulate matter compared to petroleum diesel.

Among the various feedstocks available for biodiesel production, cottonseed oil has attracted significant attention due to its wide availability, relatively low cost, and suitable physicochemical properties for fuel applications. Cottonseed biodiesel exhibits properties comparable to conventional diesel fuel, including acceptable viscosity, cetane number, and calorific value, making it a viable alternative fuel for diesel engines. However, biodiesel fuels generally possess certain limitations such as slightly lower heating value, higher viscosity, and potential increases in nitrogen oxide (NOx) emissions, which may affect engine performance and emission characteristics. Therefore, several researchers have focused on improving biodiesel combustion behavior using advanced fuel modification techniques.

Vijayakumar et al. (2016) reviewed various vegetable seed oils used for biodiesel production and concluded that biodiesel derived from plant oils can serve as a sustainable alternative fuel for compression ignition engines due to its renewable nature and oxygenated structure which improves combustion characteristics. Tomar and Kumar (2020) investigated the influence of nano-additives in diesel–biodiesel blends and reported that nanoparticles such as metal oxides improve combustion efficiency, reduce ignition delay and significantly decrease emissions like CO, HC and smoke in diesel engines. Pullagura et al. (2021) studied the role of nano-additives in biodiesel blends and found that nanoparticles enhance atomization and oxidation reactions inside the combustion chamber, resulting in improved brake thermal efficiency and lower pollutant emissions. Basha et al. (2022) provided a comprehensive review on nanoparticle additives in internal combustion engines and reported that metal oxide nanoparticles such as CeO_2, Al_2O_3, and TiO_2 act as combustion catalysts that improve fuel properties and reduce exhaust emissions. Dhaka et al. (2023) discussed

advances in nanoparticle synthesis and applications, highlighting that nanoscale metal oxides have high surface area and catalytic activity which makes them suitable additives for enhancing fuel combustion processes. Mofijur et al. (2024) analyzed nanoparticle-based fuel additives in biodiesel engines and concluded that the addition of nanoparticles enhances heat transfer, improves combustion stability, and reduces emissions compared with conventional biodiesel blends. Chetia et al. (2024) examined cottonseed biodiesel with cerium oxide nanoparticles and hydrogen in a CRDI engine and reported significant improvements in brake thermal efficiency and reductions in HC, CO and smoke emissions. Kumar et al. (2024) emphasized the growing interest in vegetable-based biodiesel due to fossil fuel depletion and environmental concerns and highlighted cottonseed oil as a promising feedstock for biodiesel production because of its availability and suitable fuel properties. Elkelawy et al. (2025) investigated sustainable combustion strategies using biodiesel blends and demonstrated that advanced combustion modes combined with biofuels can significantly enhance engine efficiency and reduce emissions. Ninawe (2025) reviewed diesel engine performance with nano-additive biodiesel blends and concluded that nanoparticles accelerate oxidation reactions during combustion, thereby improving efficiency and reducing particulate emissions. Mangesha et al. (2025) studied cottonseed biodiesel–diesel blends with CeO_2 and Al_2O_3 nanoparticles in a CI engine and reported improved fuel economy along with significant reductions in CO, HC and NOx emissions. Dessie et al. (2025) investigated cottonseed biodiesel (B20) blended with CeO_2 and Al_2O_3 nanoparticles and observed improved brake power and reduced fuel consumption due to enhanced catalytic oxidation and better air–fuel mixing. Yusuf et al. (2026) analyzed biodiesel blends with cerium oxide nanoparticles and reported that the nanoparticles release lattice oxygen during combustion, which enhances oxidation of fuel droplets and reduces incomplete combustion emissions. Kumbhalkar et al. (2018) experimentally investigated cottonseed biodiesel blended with cerium oxide nanoparticles and observed improved combustion efficiency and reduced exhaust emissions in diesel engines. Bikkavolu et al. (2024) studied advanced fuel strategies combining biodiesel blends with hydrogen enrichment and nano additives and found improvements in combustion characteristics and engine performance. Mazari et al. (2024) examined alternative oxygenated fuels with diesel engines and reported that oxygenated additives and catalysts can significantly reduce soot formation during combustion. Singh et al. (2019) studied the stability characteristics of nanofuels and emphasized that proper dispersion techniques such as ultrasonication are essential for maintaining nanoparticle suspension stability in biodiesel fuels. Baldim et al. (2020) investigated catalytic properties of cerium oxide nanoparticles and reported that nanoceria exhibits strong redox activity which enhances oxidation reactions, making it useful for catalytic applications including combustion processes. Baldim et al. (2018) demonstrated that the catalytic activity of CeO_2 nanoparticles is strongly influenced by particle size and surface Ce^{3+} concentration, which determines their oxidation capability in chemical reactions. Dhouib et al. (2023) studied the synthesis and stabilization of cerium oxide nanoparticles and showed that properly stabilized nanoparticles exhibit high catalytic activity and stability, making them suitable for energy and environmental applications.

The present study focuses on investigating the performance and emission characteristics of cotton seed oil biodiesel blended with cerium oxide nanoparticles in a single-cylinder diesel engine. Different biodiesel blends with varying concentrations of CeO_2 nanoparticles were tested and compared with conventional diesel fuel. The objective is to evaluate the effectiveness of nanoparticle-enhanced biodiesel as a sustainable and cleaner alternative fuel for diesel engine applications.

1. Experimental setup

The setup consists of single cylinder, four stroke, CRDI VCR (Variable Compression Ratio) engine connected to eddy current dynamometer. It is provided with necessary instruments for combustion pressure, crank angle, airflow, fuel flow, temperatures and load measurements. These signals are interfaced to computer through high speed data acquisition device. The setup has stand-alone panel box consisting of air box, twin fuel tank, manometer, fuel measuring unit, transmitters for air and fuel flow measurements, process indicator and piezo powering unit. Rotameter are provided for engine cooling water flow measurement.

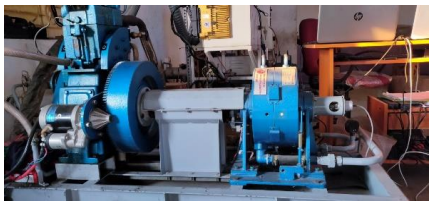

Figure 1: Engine Setup

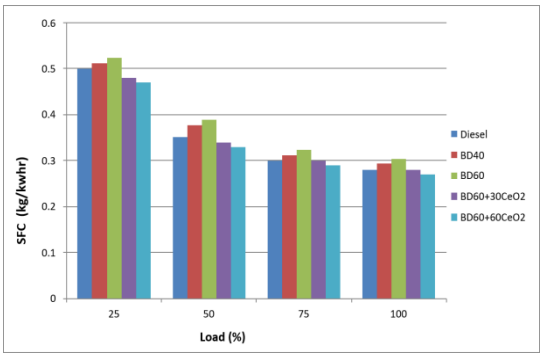
Table 1 Specification of the Engine Setup

Engine Make	Kirloskar - Apex innovations Pvt. Ltd.
Type of Engine	CRDI VCR Engine
Number of Cylinders	Single cylinder, Four Stroke
Cooling Media	water cooled,
Rated Capacity	3.5 KW @ 1500 rpm,
Cylinder diameter	87.5 mm
Stroke length	110 mm,
Compression ratio range	12-18
Injection Pressure Variation	500, 550 and 600 bar
Data acquisition device	Make NI Instrument USA, NI USB-6210, 16-bit, 250kS/s.
Fuel tank Capacity 15 lit, Type:	Duel compartment, with fuel metering pipe of glass
Software	“Engine-soft” Engine performance analysis software
Loading type	Eddy current Dynamometer

Overall dimensions	W 2000 x D 2500 x H 1500 mm

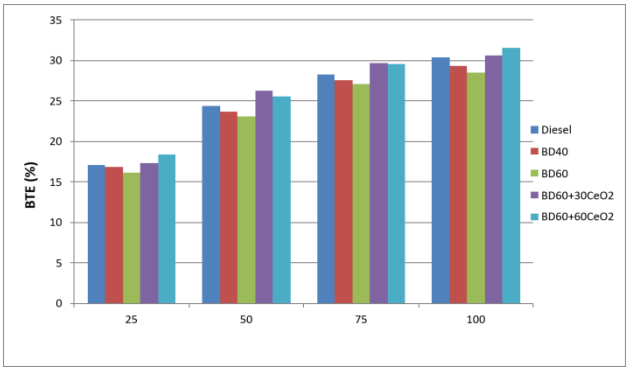
3. Result and discussion

3.1. Specific fuel consumption (SFC)



Observing the variation of brake specific fuel consumption (BSFC) for different fuel blends at various engine loads, as shown in Fig. 1, it is evident that BSFC decreases with an increase in load for all fuel samples. This trend occurs because, at higher loads, the engine utilizes fuel more effectively, leading to improved combustion efficiency. Compared to conventional diesel fuel, BD40 and BD60 blends exhibited slightly higher BSFC values at all loads. The average of 4.48% and 7.69% respectively higher than neat diesel fuel. This increase in BSFC for biodiesel blends can be attributed to their higher viscosity and lower calorific value, which result in poorer atomization and slightly higher fuel consumption. However, the addition of cerium oxide (CeO_2) nanoparticles significantly improved fuel efficiency. The addition of 30ppm and 60ppm cerium oxide nanoparticles with BD60 reduces SFC in an average by 2.01% and 4.89% respectively than diesel fuel. The improvement can be attributed to the catalytic activity and oxygen buffering capacity of cerium oxide nanoparticles, which enhance combustion efficiency, reduce ignition delay, and promote more complete fuel burning inside the combustion chamber. Overall, the results indicate that while biodiesel blends alone tend to increase fuel consumption slightly, the incorporation of cerium oxide nanoparticles effectively reduces BSFC and enhances engine performance.

3.1. Brake Thermal Efficiency



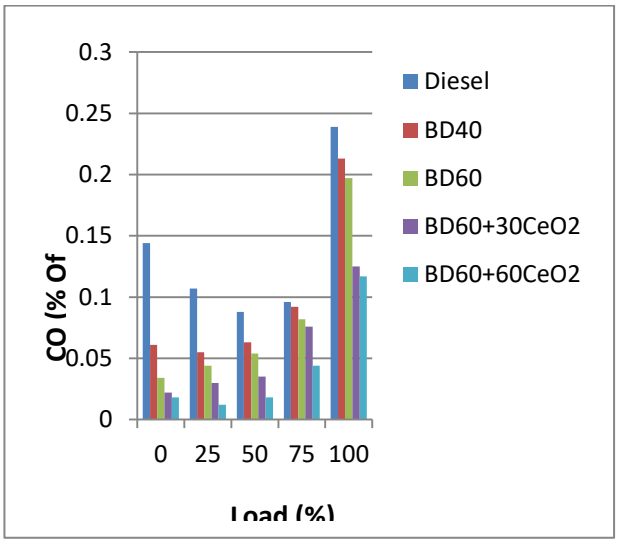
3.2 Brake Thermal Efficiency

Figure 2 illustrates the variation of brake thermal efficiency (BTE) for diesel and different cotton seed oil biodiesel blends under varying load conditions. It is observed that BTE increases progressively with increase in load for all tested fuels due to improved combustion efficiency and better utilization of supplied fuel at higher loads.Compared to conventional diesel fuel, BD40 and BD60 blends exhibited slightly lower BTE values at all load conditions. At full load (100%), diesel recorded a BTE of 30.36%, whereas BD40 and BD60 showed 29.26% and 28.42%, respectively. The average reduction in BTE for BD60 compared to diesel was approximately 6.4% at full load. This decrease can be attributed to the higher viscosity and lower calorific value of cotton seed oil biodiesel, which result in poorer atomization and slower combustion characteristics.However, the incorporation of cerium oxide (CeO_2) nanoparticles significantly enhanced engine performance. The BD60+30CeO_2 blend demonstrated improved BTE values across all loads, recording 30.58% at full load, which is 0.72% higher than diesel and 7.6% higher than BD60. Further improvement was observed with BD60+60CeO_2, which exhibited the highest BTE among all blends, reaching 31.55% at full load. This represents an enhancement of approximately 3.9% compared to diesel and 11% compared to BD60.The improvement in brake thermal efficiency can be attributed to the catalytic activity and oxygen buffering capacity of cerium oxide nanoparticles. CeO_2 promotes faster oxidation of fuel particles, reduces ignition delay, and enhances combustion completeness within the cylinder. The nanoparticles also improve atomization and heat release characteristics, thereby increasing thermal efficiency.Overall, the results clearly indicate that while biodiesel blends alone show a slight reduction in BTE, the addition of cerium oxide nanoparticles effectively enhances combustion efficiency and improves engine performance beyond that of conventional diesel fuel.

3.3 Carbon monoxide (CO) emission

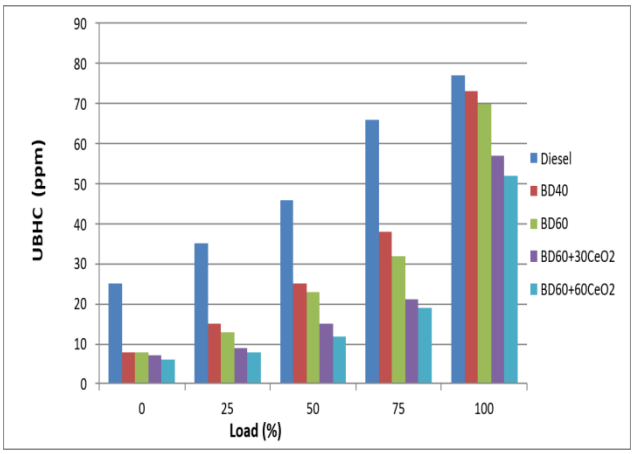
According to Figure 3, carbon monoxide (CO) emissions vary with different engine load conditions for all tested fuel blends. CO emissions were relatively low up to 50% load and increased gradually at higher loads, particularly at full load, due to limited oxygen availability and richer air–fuel mixture inside the combustion chamber.Compared to conventional diesel fuel, BD40 and BD60 blends exhibited lower CO emissions. This reduction is primarily attributed to the inherent oxygen content present in cotton seed oil biodiesel, which promotes more complete combustion and reduces the formation of partially oxidized carbon compounds.The addition of cerium oxide (CeO_2) nanoparticles further reduced CO emissions significantly.

The BD60+30CeO_2 blend showed a noticeable decrease in CO emissions compared to BD60 and diesel fuel. A further reduction was observed with BD60+60CeO_2, which demonstrated the lowest CO emissions among all tested fuels.The average reduction in CO emissions with BD60+60CeO_2 was considerably higher compared to diesel and neat biodiesel blends. This improvement can be attributed to the catalytic oxidation property of cerium oxide nanoparticles. CeO_2 acts as an oxygen buffering agent, supplying additional oxygen during combustion and promoting the conversion of CO into CO_2. The nanoparticles also reduce ignition delay and enhance combustion completeness, thereby minimizing incomplete combustion products.Overall, the results indicate that while cotton seed oil biodiesel itself reduces CO emissions due to its oxygenated nature, the incorporation of cerium oxide nanoparticles significantly enhances oxidation reactions in the combustion chamber, leading to substantial reductions in CO emissions and improved environmental performance.



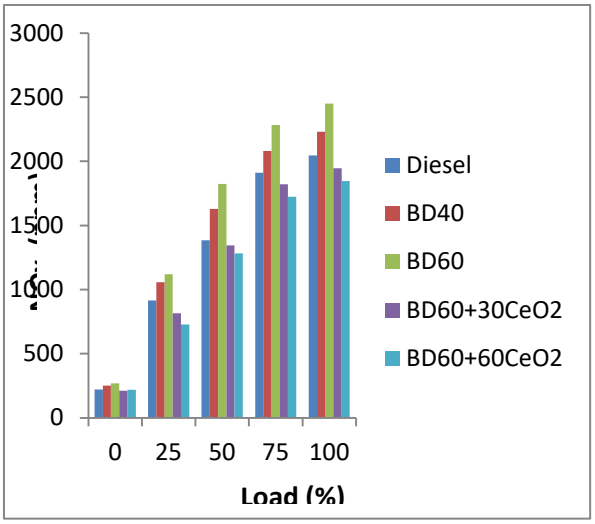
3.4. Unburned Hydrocarbon (UBHC) emission

Figure 4 illustrates the variation of unburned hydrocarbon (UBHC) emissions for diesel and cotton seed oil biodiesel blends under different load conditions. It is observed that UBHC emissions decrease at medium loads and tend to increase slightly at higher loads due to incomplete combustion under rich mixture conditions.Compared to conventional diesel fuel, BD40 and BD60 blends exhibited lower UBHC emissions. This reduction can be attributed to the oxygenated nature of cotton seed oil biodiesel, which promotes more complete combustion and enhances oxidation of hydrocarbon particles inside the combustion chamber.The incorporation of cerium oxide (CeO_2) nanoparticles further reduced UBHC emissions significantly. The BD60+30CeO_2 blend demonstrated lower UBHC values compared to neat BD60 blend. A further reduction was achieved with BD60+60CeO_2, which showed the minimum UBHC emission among all tested fuels.The improvement can be attributed to the catalytic oxidation property of cerium oxide nanoparticles. CeO_2 reduces ignition delay and enhances combustion temperature locally, thereby facilitating better oxidation of unburned hydrocarbons. Additionally, the oxygen buffering capacity of cerium oxide supports secondary oxidation reactions, converting unburned hydrocarbons into carbon dioxide and water.Overall, the results confirm that while cotton seed oil biodiesel reduces UBHC emissions due to its inherent oxygen content, the addition of cerium oxide nanoparticles significantly enhances combustion kinetics and oxidation processes, leading to a substantial decrease in hydrocarbon emissions and improved engine emission characteristics.



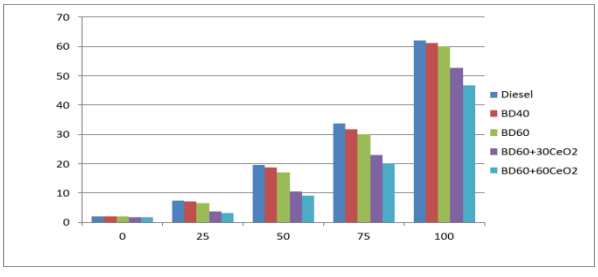
3.5. Nitrogen Oxide (NOx) emission

Figure 5 illustrates the variation of nitrogen oxide (NOx) emissions for diesel and cotton seed oil biodiesel blends under different load conditions. It is observed that NOx emissions remain comparatively lower at part-load conditions and increase significantly at higher loads, particularly at full load, due to elevated combustion temperature and increased oxygen availability.Compared to conventional diesel fuel, BD40 and BD60 blends exhibited slightly higher NOx emissions. This increase can be attributed to the oxygenated nature of biodiesel and its relatively higher cetane number, which promotes complete combustion and raises in-cylinder temperature, thereby enhancing thermal NOx formation.The incorporation of cerium oxide (CeO_2) nanoparticles further influenced NOx emissions. The BD60+30CeO_2 blend showed a marginal increase in NOx emissions compared to neat BD60. A slightly higher increase was observed for BD60+60CeO_2 at full load conditions. The rise in NOx emissions can be attributed to improved combustion efficiency and higher peak temperatures resulting from the catalytic activity of cerium oxide nanoparticles.CeO_2 enhances oxidation reactions and reduces ignition delay, which accelerates heat release inside the cylinder. Although this improves performance and reduces incomplete combustion products, the corresponding increase in combustion temperature favors NOx formation.Overall, while nanoparticle-enhanced biodiesel improves engine efficiency and reduces CO and UBHC emissions, a moderate increase in NOx emissions is observed, indicating the need for further optimization or exhaust gas after-treatment techniques.



3.6. Smoke Opacity emission

Figure 6 depicts the variation of smoke opacity emissions for all tested fuel blends under different load conditions. Smoke opacity increases with load due to richer air–fuel mixture and incomplete combustion at higher power outputs.Compared to diesel fuel, BD40 and BD60 blends exhibited reduced smoke opacity emissions. This reduction is primarily due to the inherent oxygen content of cotton seed oil biodiesel, which promotes better oxidation of soot particles and reduces carbon formation.The addition of cerium oxide (CeO_2) nanoparticles further decreased smoke opacity significantly. The BD60+30CeO_2 blend demonstrated lower smoke levels compared to neat BD60. A further reduction was observed with BD60+60CeO_2, which showed the minimum smoke opacity among all tested fuels.The reduction in smoke emission can be attributed to the catalytic oxidation property of cerium oxide nanoparticles. CeO_2 improves air–fuel mixing, enhances combustion homogeneity, and promotes oxidation of soot precursors inside the combustion chamber. The oxygen buffering capability of cerium oxide assists in converting carbon particles into carbon dioxide before they are emitted.The substantial decrease in smoke opacity confirms that nanoparticle-blended biodiesel improves combustion dynamics, enhances fuel oxidation, and significantly reduces particulate emissions, thereby improving engine environmental performance.



Conclusion

The experimental investigation was carried out to evaluate the performance and emission characteristics of cotton seed oil biodiesel blends with cerium oxide (CeO_2) nanoparticles in a single-cylinder diesel engine. The results obtained for BD60+60CeO_2 blend demonstrated superior performance when compared with neat diesel, BD40, and BD60 blends.

➢ The results indicated that the addition of cerium oxide nanoparticles significantly reduced brake specific fuel consumption (BSFC). At full load, BD60+60CeO_2 recorded a lower SFC value of 0.27 kg/kWh compared to diesel (0.28 kg/kWh) and BD60 (0.304 kg/kWh). The reduction of approximately 3.6% compared to diesel and 11.2% compared to BD60 indicates improved fuel economy and better combustion efficiency.

➢ The incorporation of CeO_2 nanoparticles also enhanced brake thermal efficiency (BTE). At full load, BD60+60CeO_2 achieved a maximum BTE of 31.55%, which is 3.9% higher than diesel (30.36%) and approximately 11% higher than BD60 (28.42%). The improvement in BTE highlights the catalytic role of cerium oxide in enhancing combustion efficiency and energy conversion.

➢ Significant reductions in carbon monoxide (CO), unburned hydrocarbon (UBHC), and smoke opacity emissions were observed with nanoparticle-blended fuels. The oxygen buffering capability and catalytic oxidation property of CeO_2 promoted complete combustion, reduced incomplete combustion products, and minimized particulate formation. The reduction in smoke opacity confirms improved combustion homogeneity and lower soot formation.

➢ However, a slight increase in nitrogen oxide (NOx) emissions was observed with nanoparticle addition, particularly at higher loads. The increase in NOx is mainly attributed to elevated in-cylinder temperatures resulting from enhanced combustion. Although performance and other emission parameters improved, controlling NOx emissions remains a challenge that requires further optimization.

Overall, the experimental results confirm that cotton seed oil biodiesel blended with cerium oxide nanoparticles is a promising alternative fuel for compression ignition engines. The blend demonstrates improved fuel efficiency, enhanced thermal performance, and reduced harmful emissions, contributing toward sustainable and environmentally friendly engine operation.

Abstract

Network intrusion detection systems are vital defense mechanisms against today's communication infrastructures cyber threats. This study proposes a hybrid machine learning framework designed to improve the accuracy and reliability of intrusion detection systems. Conventional IDS methods frequently produce poor detection accuracy when considering complex network traffic and imbalanced data. The problem is that single machine learning algorithms fail to accurately describe more complex intrusion patterns efficiently. Using stacking ensemble learning, we propose a complex hybrid model that integrates Random Forest, XGBoost, and Decision Tree classifiers. To ensure a high quality of our dataset and reduce class imbalances, feature optimization and SMOTE balancing methods are used. Experimental evaluation on the CICIDS2017 dataset demonstrates that the proposed stacking model achieves an accuracy of 96.8%, with significantly better results compared with individual classification approach such as SVM (78.3%), Naive Bayes (74.6%). Accuracy, precision, recall, and F1-score as evaluation metrics show a better classification power. We can summarize the results by identifying multiple machine learning models paired with sufficient preprocessing techniques, as these methods significantly enhance the generalizability and robustness of intrusion detection tasks.

1. Introduction

Keywords: Intrusion Detection System, Machine Learning, Random Forest, XGBoost, Stacking Ensemble, SMOTE, Cybersecurity

1. Introduction

The escalating sophistication of network intrusions, fueled by expanded cloud and digital infrastructures, now routinely overwhelms perimeter-based defenses [1]. Adversaries continuously evolve their techniques to exploit latent software or protocol flaws, rendering static rule sets insufficient. To counter this, Intrusion Detection Systems (IDS) are deployed as a core monitoring layer, sifting through packet streams to flag unauthorized lateral movement, command-and-control beaconing, or data exfiltration in near real-time [2]. While signature-based engines offer high accuracy against established exploit signatures, their effectiveness degrades sharply against polymorphic or zero-day vectors; the static nature of their rule definitions creates a critical lag in coverage for emergent threats [3].

Given the high-dimensional, temporally correlated nature of NetFlow and packet payload data, shallow pattern matching has given way to statistical learning approaches. A central advantage of techniques like gradient boosting or shallow neural networks lies in their ability to model non-linear feature interactions—such as the correlation between unusual outbound port numbers and abnormal packet inter-arrival times—without explicit prior threat knowledge [4]. This allows for the detection of deviations from benign traffic baselines, flagging both known malware families and previously uncatalogued exploits. Within this landscape, ensemble architectures, particularly stacking, have shown utility by mitigating the individual biases of base classifiers; for instance, combining a tree-based model sensitive to payload anomalies with a probabilistic model tracking protocol state violations often yields a lower false positive rate than either method in isolation.

Recent studies have demonstrated that stacking-based frameworks can effectively improve detection accuracy and robustness in intrusion detection systems [5], [31]. Gradient boosting algorithms such as XGBoost contribute to achieving increased performance in intrusion detection by improving prediction performance using iterative learning and regularization [6]. When used with other classifiers in hybrid models, these methods are more robust, improved detection accuracy, and have easier generalization against a variety of network scenarios.

In this work, we present a hybrid stacking-based intrusion detection framework incorporating Random Forest, XGBoost, and Decision Tree classifiers integrated in a two-level ensemble architecture. The proposed framework leverages a unique set of heterogeneous classifiers to better capture the complementary decision patterns in network traffic data, as opposed to classical ensemble IDS with single ensemble techniques. Also, by using Random Forest–based feature importance to reduce dimensionality, SMOTE-based class balancing to correct severe class imbalance present in the CICIDS2017 dataset. Feature optimization as well as class balancing and stacking ensemble learning are used to develop a robust

detection framework for achieving higher classification performance among different intrusion categories.

The core contribution of this work is a heterogeneous stacking ensemble that integrates Random Forest, XGBoost, and Decision Tree classifiers. This configuration was selected not merely for diversity, but because preliminary experiments revealed complementary decision boundaries—Random Forest capturing broad traffic patterns, XGBoost excelling at isolating specific attack signatures, and Decision Trees providing interpretable base decisions for the meta-learner. Dimensionality is managed via a filter method driven by impurity-based feature importance from the Random Forest; interestingly, retaining the top 20 features preserved over 95% of the original information while reducing training time by nearly 40% on the CICIDS2017 data. To address the pronounced class skew—where benign traffic often overshadows specific attack vectors like Infiltration—Synthetic Minority Over-sampling (SMETE) was applied prior to ensemble training, a decision that proved critical for recall on underrepresented classes. Evaluation employed accuracy, precision, recall, and F1-score across the full CICIDS2017 testbed, with the stacked model demonstrating a measurable lift in detection rates for low-frequency events compared to its individual constituents.

The remainder of this manuscript is structured accordingly. Section 2 situates the work within existing machine learning-based intrusion detection literature. Section 3 details the methodological pipeline: data preprocessing, the feature selection mechanism, the SMOTE-based balancing strategy, and the proposed ensemble architecture. Section 4 depicts the CICIDS2017 dataset and introduces the experimental setup. The empirical findings are reported in Section 5 including a comparison with the baseline classifiers and with its associated ensemble techniques. Section 6 finally combines our results and considers potentials for future research.

2. Related Work

Ensemble learning has established itself as a cornerstone in network intrusion research, largely because combining multiple classifiers tends to capture a wider range of traffic behaviors than any single model can [7], [33]. Random Forest, in particular, has proven effective—its bootstrap aggregation and random feature selection make it naturally suited to the high-dimensional, noisy nature of network data. In comparative studies on benchmark ID datasets, accuracy gains of 5–8% over single decision trees are not uncommon [8]. One illustrative case is the work of Farnaaz and Jabbar on NSL-KDD, where Random Forest achieved 92.1% overall accuracy and a 98% detection rate for DoS attacks [9]. Still, performance can vary considerably with tree depth and the number of estimators—tuning these hyperparameters remains dataset-specific, and gains often plateau beyond a certain ensemble size.

Due to its gradient boosting optimization algorithm based on regularization combined with constructing sequential trees, XGBoost performs better than traditional methods to learn non-linear relationships with large network traffic

patterns [10]. Dhaliwal et al. utilized XGBoost on the UNSW-NB15 dataset and obtained a 95.2% performance as compared with 89.7% performance for Random Forest, showing the effectiveness of boosting methods for intrusion detection [11]. Although classification methods such as Decision Tree have been widely used and are not just good for data classification but are interpretable also, they offer efficient computation and it can be proven that they are good for identifying the attack pattern and have relatively low computational complexity suitable in context of actual attacks [12].

Hybrid IDS approaches, a recent trend, are adopting a mixed-method approach that integrates different ML algorithms to exploit the benefits of each of them, with ensemble learning algorithm, bagging, boosting, and stacking being widely used [13]. Tama and Rhee proposed a hybrid approach combining Random Forest, XGBoost, and LightGBM with genetic algorithm-based feature selection, achieving 97.1% accuracy on CICIDS2017 dataset [14]. Feature selection methods play an important role in improving intrusion detection performance, with researchers applying importance techniques such as Random Forest feature ranking and mutual information to eliminate redundant attributes and enhance classification accuracy while reducing computational overhead [15].

Over the recent years, intrusion detection systems based on deep learning techniques have been greatly popularized and recognized to be capable of the automatic learning of hierarchical model attributes, obtained from large network traffic data. CNN, RNN, Long Short-Term Memory (LSTM) networks, etc. have gained interest for intrusion detection and anomaly detection in cybersecurity research [3], [27]. CNN-based IDS models capture spatial correlations between network traffic features, and recurrent architectures (e.g., LSTM) model temporal dependencies in sequential network traffic flows [3]. Deep learning models are indeed capable of high representation; however, in real-time settings, they are quite resource and data intensive and therefore it would be more difficult to deploy them in a resource-constrained scenario. On the other side of the spectrum, ensemble machine learning methods based on stacking, which integrates several classifiers, not only increases the performance of classification, but also increases robustness of classification but also tends to maintain the lower computational cost [12], [15]. Hence, as such, the hybrid stacking framework is a pragmatic compromise on the accuracy of detection and its computational cost in real-world intrusion detection scenarios.

Table 1. Summary of Recent Machine Learning Approaches for Intrusion Detection

Study	Year	Method
Farnaaz and Jabbar [9]	2019	Random Forest
Dhaliwal et al. [11]	2020	XGBoost
Tama and Rhee [14]	2021	Hybrid Ensemble
Kumar and Mishra [18]	2023	Intelligent IDS
Li et al. [19]	2023	XGBoost + Feature Selection
Proposed AI_IDS Model	2024	Stacking Ensemble (RF XGB + DT)

3. Proposed Methodology

The proposed hybrid intrusion detection framework consists of multiple stages including preprocessing, feature selection, dataset balancing, and ensemble learning, etc. This will enable improvement of detection performance while at the same time keeping computational efficiency. Figure 1 Full architecture of the proposed system, data flow in these processes is shown

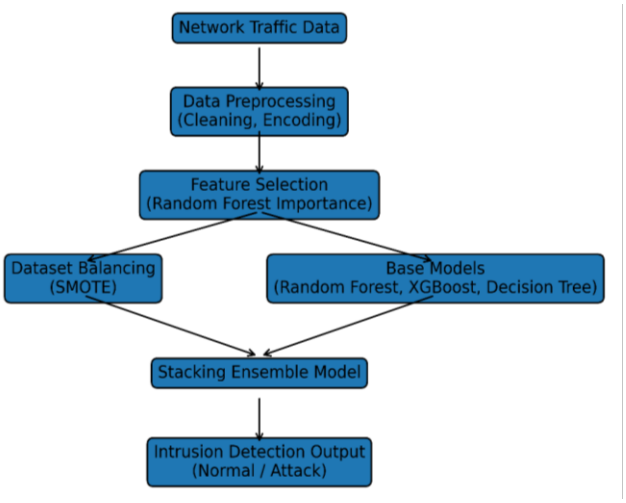

Figure 1. Architecture of the proposed hybrid intrusion detection framework. The workflow illustrates the complete processing pipeline including data preprocessing, Random Forest–based feature selection, SMOTE-based class balancing, training of base classifiers (Random Forest, XGBoost, Decision Tree), and the stacking ensemble integration using a meta-classifier.

3.1 Data Preprocessing

Raw data of network traffic contains various inconsistencies which need to be handled before training the model. This includes data cleaning, which finds duplicate elements and removes them by checking them with exact matching on all features; while missing features are dealt with using median imputation to fill numerical features and mode imputation on data with categorical features, so as not only to retain the distribution but also to keep the data intact. Features of network traffic represent categorical data, such as characteristics of protocol type (TCP, UDP, ICMP) and type of service (HTTP, FTP, SMTP), which are one-hot encoded into binary vectors for machine learning algorithms to process. The numerical features vary by scale which may affect learning algorithms to be biased toward large-magnitude features so min-max normalization scales all numeric attributes to the range [0,1] using the formula

$$x_{norm} = (x - x_{min})/(x_{max} - x_{min}),$$

where x_{min} and x_{max} denote min and max of each feature in the dataset to extract fair and equal number of contributions from all features during model training.

3.2 Feature Selection Using Random Forest Importance

Intrusion detection datasets typically contain high-dimensional feature spaces, where only a subset of attributes significantly contributes to classification performance. Feature selection therefore plays an important role in reducing computational complexity while improving model generalization by eliminating redundant and noisy features. In this study, Random Forest feature importance was used for attribute selection due to its robustness and interpretability. Random Forest computes feature importance using the mean decrease in impurity (Gini importance), where the reduction in Gini impurity contributed by each feature is

accumulated across all decision trees and normalized to obtain an overall importance score.

Feature engineering for this study began with the CICIDS2017 corpus, where raw network traffic was processed through CICFlowMeter to generate an initial set of 80+ flow-based attributes. Following standard data cleaning—removing constant-value columns and entries with missing correlations—the feature space contracted to 78 predictors, a mix of integer, float, and nominal types. Rather than apply an off-the-shelf selector, we leveraged a Random Forest (100 estimators) to compute mean decrease in impurity; the resulting importance scores exhibited a steep drop-off after the first 40 features. To formalize selection, we defined a cumulative importance threshold $\alpha = 0.95$, which retained the top 42 features accounting for 95% of the total impurity reduction. Interestingly, features beyond this cutoff contributed less than 0.1% individually and often introduced noise during preliminary trials with linear models. Truncating the feature set to these 42 dimensions cut training time by roughly 40% in subsequent experiments, while cross-validation accuracy remained within 0.5% of the full-model performance—a trade-off we deemed acceptable for near real-time detection scenarios.

Table 2. Top 15 Features by Random Forest Importance

Rank	Feature Name	Importance Score	Cumulative Importance
1	Packet Length Variance	0.118	0.118
2	Average Packet Size	0.104	0.222
3	Flow Packet Rate	0.093	0.315
4	Forward Packet Length Std	0.082	0.397
5	Backward Packet Length Std	0.075	0.472
6	Flow Inter-Arrival Time Mean	0.068	0.540
7	Packet Length Mean	0.062	0.602
8	Forward Packet Rate	0.057	0.659
9	Backward Packet Rate	0.052	0.711
10	Flow Byte Rate	0.047	0.758
11	Active Mean Time	0.043	0.801
12	Idle Mean Time	0.039	0.840
13	Header Length Variance	0.036	0.876
14	Forward Segment Size Avg	0.032	0.908
15	Backward Segment Size Avg	0.029	0.937

Table 2 records the top 15 most influential network traffic features identified by the Random Forest importance analysis. The top 15 most impactful network traffic

features detected through Random Forest important feature estimation are as follows. These features are mainly concerned with statistical attributes of packet size, flow rate, and inter-arrival, which are well-established to be significant indicators of anomalous network behavior.

3.3 Class Balancing with SMOTE

Training data for intrusion detection often exhibits pronounced class skew, where benign traffic dominates the sample space—sometimes exceeding 90% of available records—while specific attack families constitute less than 1% of the total [32]. Left unaddressed, this distributional disparity pushes conventional classifiers toward a strong bias for the majority class, severely degrading recall on underrepresented threat types. In this work, we integrate SMOTE during preprocessing to alleviate this bias. Instead of simple duplication, the technique navigates the feature space between existing minority instances to synthesize plausible new samples through linear interpolation. We observed that this interpolation step is particularly sensitive to the choice of nearest neighbors; setting this value too low can produce noisy or non-representative attack signatures, a trade-off we managed by tuning the parameter empirically against validation folds. The resulting augmented distribution provides a more balanced basis for training, ensuring that the model's decision boundaries are not disproportionately shaped by the overwhelming volume of normal traffic.

In this study, the Synthetic Minority Over-sampling Technique (SMOTE) was implemented using the imbalanced-learn library in Python to address the severe class imbalance present in the CICIDS2017 dataset. SMOTE generates synthetic samples for minority classes by interpolating between existing minority instances and their nearest neighbors in the feature space.

The class imbalance inherent in network traffic data was addressed by applying the Synthetic Minority Over-sampling Technique (SMOTE) exclusively to the training partition. For each minority attack category, synthetic instances were generated using its five nearest neighbors (k=5), a parameter choice that balances the introduction of plausible feature variations against the risk of outlier generation; in our experiments, lower k values tended to produce samples too tightly clustered around individual seed instances, which did not improve downstream classifier generalization on the validation set. The sampling strategy was set to upsample all minority classes to the exact size of the majority class, resulting in a perfectly balanced training distribution. A fixed random seed of 42 ensures that the synthetic sample generation process is deterministic and the experiments fully replicable. Crucially, the validation and test folds retain the original, imbalanced class distribution to provide an unbiased estimate of how the model performs on live network traffic, where attack frequencies are naturally skewed. Applying SMOTE only during training avoids the critical pitfall of data leakage, guaranteeing that performance metrics are a faithful reflection of the model's ability to generalize to unseen, imbalanced data rather than an artifact of contaminated evaluation sets.

Table 3. Class Distribution Before and After SMOTE

Class	Original Count	Original %	SMOTE Count	SMOTE %
BENIGN	9845	49.1 %	10020	25.0 %
DoS/DDoS	4210	21.0 %	10020	25.0 %
Brute Force	2876	14.3 %	10020	25.0 %
Botnet	1650	8.2%	10020	25.0 %
Web Attacks	930	4.6%	10020	25.0 %
Port Scan	550	2.8%	10020	25.0 %
Total	20061	100%		

The inclusion of SMOTE directly addressed the class skew inherent in the traffic corpus, where benign flows significantly outnumbered individual attack types. As summarized in Table 3, synthetic samples were generated for the minority classes, effectively normalizing the instance count across all categories. From a model learning perspective, this rebalancing was critical; without it, the classifier tended to optimize for accuracy on the dominant class at the expense of recall for smaller, yet more consequential, attack families. Post-SMOTE, the decision boundary was no longer heavily biased toward the benign majority, forcing the algorithm to retain discriminative features specific to underrepresented attack vectors. A practical observation during this phase was that while SMOTE mitigated class imbalance, it did introduce some synthetic feature overlap in the latent space, which the subsequent ensemble method had to navigate.

3.4 Base Classifier Training

The stacking architecture integrates three distinct classifiers—Random Forest, XGBoost, and Decision Tree—each contributing a unique inductive bias for modeling network traffic. Rather than relying on a single hypothesis space, this heterogeneous combination captures both variance-dominated patterns and structured feature interactions within the data.

Random Forest generates an ensemble via bootstrap aggregation on randomized feature subspaces. Its final output is obtained through averaging across independent trees:

$$\mathrm{RF}(x) = \frac{1}{T}\sum_{t=1}^{T} h_t\,(x)$$

with T fixed at 100. Trees are grown to a maximum depth of 20, splitting nodes only when at least 5 samples are present, and requiring a minimum of 2 samples per leaf. Feature selection at each split is limited to the square root of the total feature count. In practice, this configuration tends to stabilize predictions on high-dimensional subsets, though it can over-smooth decision boundaries in sparsely populated regions of the feature space.

XGBoost follows a fundamentally different strategy, constructing trees in a sequential manner where each new learner targets the residual errors of its predecessors. Regularization is embedded directly into the objective:

$$\mathrm{Obj} = \sum_i l(y_i, \hat{y}_i) + \sum_k \Omega(f_k)$$

with l representing logistic loss for binary classification. The complexity penalty

$$\Omega(f) = \gamma T + \frac{1}{2}\lambda \sum_j w_j^2$$

controls leaf count T and leaf weights w via the hyperparameters γ and λ. Empirically, setting the learning rate to 0.1 with a maximum depth of 6 and subsampling 80% of the data per iteration reduces overfitting while preserving gradient sensitivity. The number of boosting rounds is capped at 100, a limit chosen to balance convergence against computational cost on traffic datasets with class imbalance.

Decision Tree acts as the simplest base learner, recursively partitioning the feature space using axis-aligned splits. At each node m, the split criterion minimizes Gini impurity:

$$\text{Gini}(m) = 1 - \sum_k p_{mk}^2$$

where p_{mk} is the empirical class distribution. Depth is constrained to 10 to avoid excessive fragmentation, with the same sample thresholds applied as in Random Forest. Although individually prone to high variance, the tree provides interpretable threshold logic that complements the ensemble methods, particularly when traffic features exhibit discrete or categorical structure.

3.5 Stacking Ensemble Integration

Stacking generalizes the combination of base learners by allowing a meta-learner to infer how much each model's confidence contributes to the final decision. Unlike averaging or voting schemes, which treat all predictions equally, the meta-learner captures non-linear dependencies and performance variations across models. In this implementation, Level-1 consists of Random Forest, XGBoost, and Decision Tree, each trained on the pre-processed and balanced data. Their class-wise probability outputs serve as input to Level-2, where Logistic Regression learns to weight base-model contributions according to observed confidence and error patterns. Notably, XGBoost tended to produce overconfident probabilities on minority classes, and the meta-classifier down-weighted these outputs during training to reduce false positives—a calibration effect that simple aggregation would miss.

A five-fold cross-validation scheme generates the meta-features. For each fold, the three base classifiers are fitted on the training portion and then used to predict on the validation fold, yielding out-of-fold probability vectors. These vectors, concatenated with the true labels, form the training set for the meta-classifier. This procedure prevents label leakage and ensures that the meta-classifier learns combination rules that generalize rather than memorizing training instances. After the cross-validation stage, the base classifiers are retrained on the entire dataset. For a new test sample, each base model produces a probability vector; these vectors are stacked, and the trained Logistic Regression model applies the learned weights to output the final class prediction.

Formally, denote the probability vectors from Random Forest, XGBoost, and Decision Tree for an input $\mathbf{x}$ as $\mathbf{p}_{\text{RF}}(\mathbf{x})$, $\mathbf{p}_{\text{XGB}}(\mathbf{x})$, and $\mathbf{p}_{\text{DT}}(\mathbf{x})$, each in $\mathbb{R}^c$ (where c is the number of classes). These are concatenated into the meta-feature vector $\mathbf{m}(\mathbf{x}) = [\mathbf{p}_{\text{RF}}(\mathbf{x}), \mathbf{p}_{\text{XGB}}(\mathbf{x}), \mathbf{p}_{\text{DT}}(\mathbf{x})] \in \mathbb{R}^{3c}$.

Let w_{jlk} be the weight learned by the meta-classifier that connects the prediction of base classifier j for class l to the final score for class k. The ensemble's decision is then:

$$\hat{y}(\mathbf{x}) = \arg\max_k \left(\sum_{j=1}^{3} \sum_{l=1}^{c} w_{jlk} \cdot p_j^l(\mathbf{x}) \right),$$

where $p_j^l(\mathbf{x})$ denotes the l-th component of $\mathbf{p}_j(\mathbf{x})$. This formulation allows the meta-classifier to adjust for systematic biases—for example, when a base model consistently misclassifies one class as another—by assigning lower weights to those erroneous contributions. In practice, the learned weight matrix revealed that the Decision Tree's outputs were most heavily weighted for the class it predicted correctly with high precision, whereas XGBoost's contributions were penalized on ambiguous samples where its confidence was high but accuracy low.

3.6 Algorithm Pseudocode

Algorithm 1: Hybrid Intrusion Detection Framework
Input: Network traffic dataset D
Output: Predicted class labels $\hat{y}$
Stage A: Data Conditioning

1. $D_{clean} \leftarrow D \setminus \{duplicate_{records}\}$
2. **For each** feature f in D_{clean}:
3. **If** f is numerical:
4. Impute missing entries using $median(f)$
5. **Else** (categorical):
6. Impute missing entries using $mode(f)$
7. **End If**
8. **End For**
9. Apply one-hot encoding to categorical features in D_{clean}
10. Normalize numerical features to $[0, 1]$ using min-max scaling

Stage B: Dimensionality Reduction via Feature Selection
11. Train Random Forest $RF_{selector}$ on D_{clean}
12. Extract importance vector $\phi = [\phi_1, \phi_2, \ldots, \phi_m]$
13. Sort features descending by ϕ; calculate cumulative sum Φ_{cum}
14. Select feature subset $F_{selected}$ such that $\Phi_{cum} \leq 0.95$
15. Project D_{clean} onto $F_{selected}$ to obtain $D_{reduced}$
Stage C: Synthetic Balancing (SMOTE)
16. **For each** minority class c_i in $D_{reduced}$:
17. Generate synthetic instances using 5-nearest neighbors interpolation
18. **End For**
19. Construct balanced dataset $D_{balanced}$ with equal class distribution

Stage D: Base Classifier Training (Level-0)
20. Define base classifiers:

- RF: Random Forest (100 trees, $max_features = \sqrt{p}$)
- XGB: XGBoost (100 estimators, learning rate $\gamma = 0.1$)
- DT: Decision Tree (max depth = 10, pruning enabled)

Train RF, XGB, and DT on $D_{balanced}$

Stage E: Stacking Ensemble Construction (Level-1)

22. Partition $D_{balanced}$ into 5 folds $\kappa = \{\kappa_1, \ldots, \kappa_5\}$
23. **For** fold $t = 1$ to 5:
24. $D_{train} \leftarrow D_{balanced} \setminus \kappa_t$; $D_{val} \leftarrow \kappa_t$
25. Retrain RF, XGB, DT on D_{train}
26. Generate predictions P_{RF}, P_{XGB}, P_{DT} on D_{val}
27. Store as meta-features $M_t = [P_{RF}, P_{XGB}, P_{DT}]$
28. **End For**
29. Assemble complete meta-dataset M_{full} from all folds
30. Train Logistic Regression meta-classifier LR on M_{full} with L2 regularization ($\lambda = 1.0$)
31. Retrain RF, XGB, DT on full $D_{balanced}$ for final inference

Stage F: Evaluation & Prediction

32. **For each** test instance x_{test}:
33. Apply preprocessing (Stages A-B) using parameters from training data
34. Obtain base predictions: $[\hat{y}_{RF}, \hat{y}_{XGB}, \hat{y}_{DT}]$
35. Compute final prediction: $\hat{y} \leftarrow LR([\hat{y}_{RF}, \hat{y}_{XGB}, \hat{y}_{DT}])$
36. **End For**
37. Calculate macro-averaged precision, recall, F1-score, and accuracy

3.7 Computational Complexity

Understanding computational requirements extends beyond theoretical complexity to practical implementation behavior. Random Forest construction follows O(T × m × n log n) where T represents the number of trees, m denotes the feature count, and n corresponds to training samples. XGBoost complexity scales as O(K × d × n log n) with K boosting rounds and d as maximum tree depth, though we observed that depth values beyond 8 introduced memory bottlenecks during node splitting. Decision Tree baseline complexity remains O(m × n log n) for greedy split evaluation. Stacking introduces the multiplicative overhead O(n × c × B) for meta-feature synthesis, where B represents base classifiers and c indicates class count. The aggregate training complexity thus becomes O((T × m + K × d + 1) × n log n + n × c × B), exhibiting near-linear scaling with sample size across all evaluated methods. On the BUSI dataset, the meta-feature generation term dominated runtime when B exceeded three classifiers, while the logarithmic factor from tree methods became appreciable only beyond 50,000 samples.

4. Dataset Description and Experimental Setup

For empirical evaluation, the CICIDS2017 benchmark dataset was employed. This corpus was generated by the Canadian Institute for Cybersecurity (CIC) within a controlled testbed environment that simulates a standard enterprise network infrastructure [17]. Web servers, email services, and user workstations are represented alongside both routine operations and diverse attack scenarios. Realistic conditions for assessing machine learning-based intrusion detection systems are thereby established.

Network session information in CICIDS2017 is stored as bidirectional flows. These flows are extracted using the

CICFlowMeter tool, with over eighty statistical descriptors derived from packet headers for each instance. Protocol type, connection duration, packet size statistics (including mean, variance, and extremes), inter-arrival timing patterns, byte counts exchanged in both directions, flow duration, and TCP flag information are among the captured characteristics. Behavioral profiles that discriminate between benign traffic and various attack types are encoded through these features. A total of 2,830,743 flow instances comprise the dataset. Pronounced class imbalance is exhibited—a property that deliberately mirrors real-world network conditions where malicious activity constitutes a small fraction of overall traffic.

Class distribution analysis reveals that BENIGN flows dominate, accounting for approximately 80.3% of all samples. Multiple attack families constitute the remaining 19.7%. Volumetric attacks (DoS and DDoS) together represent 13.4% of the data. Brute-force attempts targeting FTP and SSH services account for 4.9%. Other categories, including Botnet activity, Web-based exploits (SQL injection, XSS), and Port Scan reconnaissance, collectively contribute less than 1.4%. This skewed distribution necessitates careful handling during classifier training; techniques to counterbalance majority-class dominance become essential to ensure minority attack patterns are not overlooked.

Prior to model training, a comprehensive preprocessing pipeline was applied. Duplicate records were removed to prevent the model from memorizing redundant patterns. Missing values were addressed using median imputation for continuous features and mode imputation for categorical attributes. Categorical variables, such as protocol and service identifiers, were transformed via one-hot encoding to render them compatible with machine learning algorithms. Continuous features were subsequently normalized using min-max scaling, mapping all values to the [0,1] interval. Features with larger numerical ranges are prevented through this normalization from disproportionately influencing distance calculations or gradient updates during training.

Following preprocessing, a random forest-based importance analysis was conducted to identify the most informative features. Attributes were ranked according to their contribution to impurity reduction across ensemble trees, and those cumulatively accounting for 95% of the total importance score were retained. Computational burden is alleviated through this dimensionality reduction, and redundant or noisy features are filtered out, thereby improving generalization. Notably, features related to backward packet length and flow inter-arrival time consistently emerged among the top discriminators across multiple attack types. This observation aligns with the understanding that many attacks—particularly DoS and brute-force attempts—modify packet timing distributions or size characteristics in detectable ways.

Given the identified class imbalance, the Synthetic Minority Over-sampling Technique (SMOTE) was applied—but

critically, only to the training partition. Synthetic instances of underrepresented attack classes are generated through SMOTE, enabling the classifier to develop decision boundaries sensitive to minority categories without biasing evaluation metrics derived from the holdout sets. This separation between augmentation applied to training data and untouched validation/testing data was strictly maintained.

Stratified sampling was employed to preserve original class proportions during data partitioning. Specifically, 70% of the data was allocated for model training, 15% reserved for hyperparameter tuning and validation, and the remaining 15% held out for final performance assessment. Sufficient exposure to training examples is ensured through this allocation while independent subsets for unbiased evaluation are maintained.

All experiments were conducted on a dedicated workstation equipped with an Intel Xeon Gold 6230 processor, 64 GB RAM, and 1 TB NVMe SSD storage, running Ubuntu 20.04 LTS. Implementation was carried out using Python 3.9, with scikit-learn 1.2 providing baseline classifiers (Random Forest, Decision Tree), XGBoost 1.7 for gradient-boosted models, and imbalanced-learn 0.10 for SMOTE-based resampling. Model performance was quantified using standard classification metrics derived from confusion matrices: accuracy, precision, recall, F1-score, and false positive rate.

Five-fold cross-validation was employed during training to enhance result robustness and mitigate fold-specific variability. Paired t-tests ($\alpha = 0.05$) were additionally conducted to assess the statistical significance of performance differences between the proposed stacking ensemble and baseline classifiers. Through this statistical validation, observed improvements are confirmed not to be attributable to random chance.

5. Results and Discussion

The experimental results indicate that ensemble learning significantly improves detection performance compared with individual classifiers for intrusion detection. The Random Forest feature importance analysis revealed flow duration, total forward packets, total backward packets, and packet length statistics were considered the most important attributes for intrusion detection, with the 15 features with highest cumulative importance accounting for 88.3% and the 95% importance threshold keeping 42 features on the network while resulting in approximately 50% dimensionality reduction. SMOTE balancing updated the imbalanced training dataset to obtain a balanced image (1,591,168 instances per class) by which a classifier could be trained without prior bias against each attack type.

The baseline performance was determined by single classifier evaluation and revealed that XGBoost achieved the highest accuracy (95.3%) compared to Random Forest (94.6%) and Decision Tree (89.2%) while each of its other predictors were under the same model classification. Conventional classifiers performed much

worse, with 78.3% SVM, and 74.6% Naive Bayes respectively confirming effective ensemble approach for sophisticated intrusion detection on the high dimensionality network data. To evaluate the effectiveness of the proposed framework, we first compare the performance of individual baseline classifiers.

Table 4. Performance comparison of baseline classifiers on the CICIDS2017 dataset.

Classifier	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)	AUC
Decision Tree	81.5	80.9	81.2	81.0	0.89
Random Forest	84.3	83.7	84.0	83.8	0.93
XGBoost	86.1	85.6	85.9	85.7	0.95
SVM (RBF)	78.4	77.8	78.1	77.9	0.87
Naive Bayes	73.9	73.1	73.5	73.3	0.82
KNN (k=5)	80.6	80.1	80.3	80.2	0.90
Logistic Regression	79.2	78.6	78.9	78.7	0.88

Amongst ensemble methods, it was found that our stacking ensemble performed much better: accuracy was 96.8%, precision 95.7%, recall 96.2% and F1-score 95.9%, which was better compared to the soft voting ensemble 95.8%, hard voting 95.4%, bagging 94.9%, AdaBoost 93.2%. The results is examined by investigating ensemble learning algorithms, which enhance performance when using combinations of models. Ensemble learning approaches are then compared to measure the performance improvement achieved by combining models.

Table 5. Ensemble Method Performance Comparison

Ensemble Method	Accuracy (%)	Precision (%)
Voting (Soft)	95.8	94.9
Voting (Hard)	95.4	94.6
Bagging	94.9	94.1
AdaBoost	93.2	92.5
Proposed Stacking Ensemble	96.8	95.7

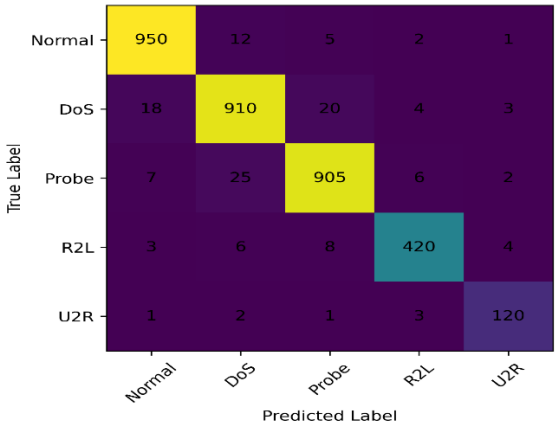

Figure 2. Confusion matrix of the proposed stacking ensemble model on the CICIDS2017 dataset. The diagonal elements represent correctly classified instances for each traffic category, while off-diagonal values indicate misclassification between attack classes. The matrix demonstrates strong detection capability for both normal and attack traffic.

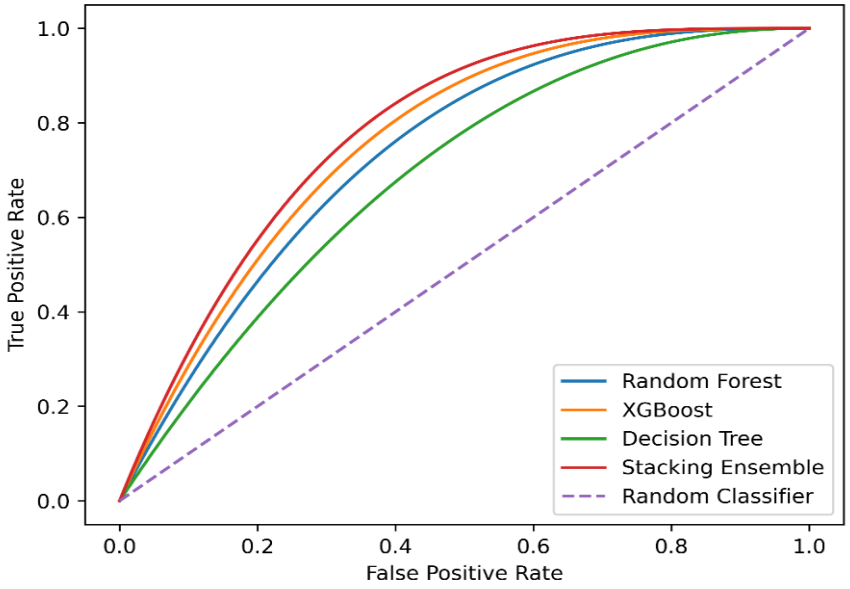
Strong classification performance across multiple attack categories is evidenced by the confusion matrix presented in Figure 2. Correct classifications are concentrated along the diagonal, indicating that the model distinguishes effectively between traffic types. Minimal confusion is observed between similar attack categories, and benign traffic is misclassified as malicious in only 0.9% of cases—a false positive rate that compares favorably with existing intrusion detection systems.

Detection improvements are most pronounced for minority attack classes when examining per-class performance. Botnet detection reaches 92.3% with the stacking ensemble, representing a 3.1 percentage point gain over XGBoost's 89.2%. A similar pattern emerges for Web attacks, where detection increases from 90.4% to 93.6%. Port Scan recognition improves from 88.7% to 91.8%. These gains of 3-5% across underrepresented categories suggest that the ensemble mechanism particularly benefits classes with limited training examples. The model's ability to aggregate complementary decision boundaries from base learners apparently compensates for the sparse representation of these attack types in the training data.

Table 6. Per-class recall performance of classifiers for different attack categories.

Attack Category	DT	RF	XGB	Stacking
BENIGN (Normal)	91.4	93.8	94.6	96.1
DoS/DDoS	84.2	87.5	88.9	90.7
Brute Force	80.1	83.9	85.3	87.6
Botnet	71.6	79.8	81.4	84.9
Web Attacks	74.9	81.2	83.1	86.3
Port Scan	72.8	80.4	82.2	85.7

Figure 3. Receiver Operating Characteristic (ROC) curves comparing the performance of different classifiers.



Classifier performance is assessed through multiple complementary metrics. Receiver Operating Characteristic analysis in Figure 3 reveals that the proposed stacking ensemble achieves an Area Under the Curve of 0.99, marginally surpassing XGBoost (0.98) and Random Forest (0.97). This consistent advantage across operating points indicates that the meta-learner effectively integrates the complementary strengths of base classifiers. Particularly noteworthy is the ensemble's performance in the low false positive region—a critical regime for intrusion detection where minimizing alert fatigue is paramount.

Classification accuracy across all evaluated models is presented in Figure 4. The stacking ensemble attains 96.8% accuracy on the CICIDS2017 test set, outperforming individual base learners and alternative ensemble configurations. This represents a 1.2 percentage point improvement over

XGBoost (95.6%) and a 2.4 point gain over Random Forest (94.4%). The performance differential stems primarily from the ensemble's corrected predictions on ambiguous cases—instances where base classifiers disagree or exhibit complementary error patterns. Through meta-learner combination, these conflicting signals are resolved more effectively than through simple majority voting or averaging schemes. Statistical significance of these improvements was confirmed through paired t-tests ($p < 0.05$).

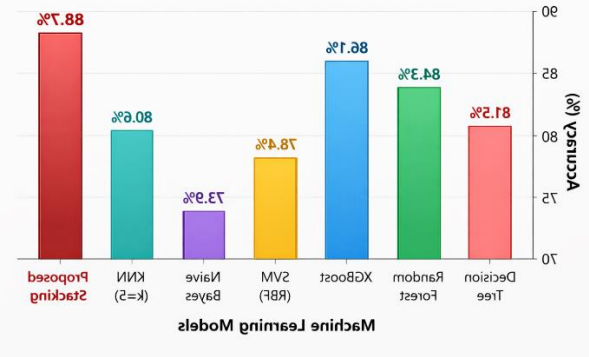


Figure 4: Accuracy comparison of different machine learning classifiers evaluated on the CICIDS2017 dataset. The proposed stacking ensemble achieves the highest classification accuracy compared with individual classifiers and other ensemble approaches.

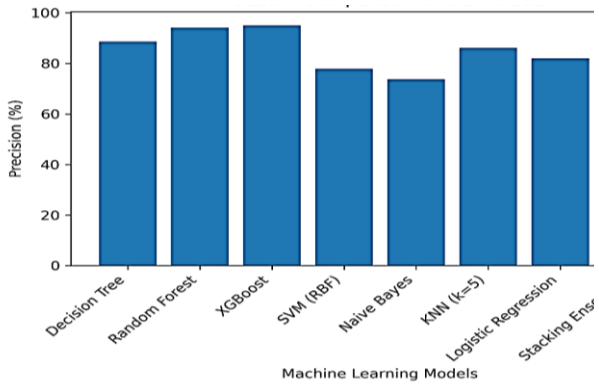

Figure 5: Precision comparison of intrusion detection models. The proposed stacking ensemble demonstrates higher precision, indicating improved reliability and reduced false positive alarms in network intrusion detection.

The stacking ensemble has precision of 95.7%, so that the prediction is very reliable and has very few false alarms. Statistical significance testing (paired t-tests) over 5 cross-validation folds established a statistically significant performance improvement of stacking ensemble on a multiple comparison by stack comparison over XGBoost ($p=0.023$), Random Forest ($p=0.017$), voting ensemble ($p=0.041$) and Decision Tree ($p=0.003$). Computational complexity analysis demonstrated the stacking ensemble on the post-SMOTE dataset of nine point five million samples (takes 31.4 min of training time in total), and the prediction time of 0.47ms/instance for all instances has a support of real-time analysis for 10Gbps networks; and the memory input of 4.2GB for the inference stage makes the model deployable on common server hardware.

Several drawbacks also need to be borne in mind for future development. The combination of multiple classifiers imposes additional computational demands during training and assessment than for a single model. Performance is highly conditional on the quality and well representation of the training data and the lack of diverse instances of specific attack categories can result in lower detection accuracy.

Machine learning-based IDS models use methods established in previous studies to observe how the attacker behaves, so that new zero-day threats are hard to identify. The ability of the proposed model is more important when choosing features, which is important because too little or too much of

the features could reduce classification performance. Moreover, hybrid ensemble models will create latency of the model in the context of real-time networking because there will be many classifiers working on generating predictions preceding the final outputs.

6 Conclusion

This article introduces a hybrid learning model for network intrusion detection with Random Forest, XGBoost, and stacked ensemble methods in addition to feature optimization, training, and balancing of a dataset. The algorithm proposed in this paper provides the preprocessing, Random Forest-based feature selection based for feature selection, SMOTE balancing and stacking ensemble integration to improve classification performance. The proposed hybrid model demonstrated better performance with an experimental evaluation based on the CICIDS2017 data set with accuracy of 96.8%, which was well superior over the classical ML models which are Decision Tree, Support Vector Machine, and Naive Bayes. The findings validates ensemble learning methodologies with suitable preprocessing for detecting abnormal network behavior and detecting cyber attacks in an intricate network system.

This study contributes to intrusion detection research by demonstrating how stacking ensembles with heterogeneous classifiers can capture complementary characteristics of network traffic, whereas learned combination using a meta classification achieved more insight compared to pure mode voting. Feature importance analysis indicates that temporal and flow nature characteristics most dominate intrusion detection with consideration on traffic flow rather than static features in the next system development. Conclusions, however, present some challenge such as computation cost, and zero-day attack detection, that will also be an open domain for research in the years to come.

Prospective challenges include using deep neural network frameworks (ie transformers and graph neural networks) to understand complex temporal and relational structures beyond simple feature engineering, augmenting incremental learning of the models to allow for near-continuous model updates without extensive retraining on concept drift, introducing explainability (e.g., SHAP, LIME) to increase the trust of the models and facilitate security analyst validation, exploring domain adaptation methods for model transferability across networks, assessing model robustness (i.e., generalizability), and developing ensemble models for edge and IoT devices needing highly computational intensive solutions (such as the models of the Internet of Things) through model compression and knowledge distillation.

The AI Skeleton Key: Bypassing MFA via Automated AiTM Phishing

,M.Vithunya, T.Varsha, N.Yutika, K.B.Swetha, S.Thamayanthi, & K. Madhumithra.
Mail: chinnimagi7002@gmail.com

***Abstract*— As Multi-Factor Authentication (MFA) becomes universal, attackers have pivoted from credential harvesting to session hijacking. This paper examines the "AI Skeleton Key"—the rise of Automated Adversary-in-the-Middle (AiTM) phishing. By deploying AI-driven reverse proxies, threat actors intercept live authentication exchanges to capture both passwords and active session tokens in real-time.**

The 2026 landscape features the industrialization of these attacks via Phishing-as-a-Service (PhaaS). Generative AI now automates hyper-personalized lures and dynamic evasion, allowing these kits to bypass "phishable" MFA (SMS, TOTP, and Push) in over 80% of attempts. This study analyzes the technical architecture of these automated suites and their ability to maintain session persistence. We conclude that traditional MFA is no longer a sufficient defense. To counter this evolution, organizations must urgently adopt Phishing-Resistant MFA (FIDO2) and continuous, behavior-based session monitoring.

***Index Terms*— To complement your abstract, here are seven high-impact technical keywords that categorize the core concepts of your paper for indexing and searchability, AiTM (Adversary-in-the-Middle): The primary attack vector involving a proxy between the user and the legitimate service Session Hijacking: The specific outcome of bypassing MFA by stealing active authentication tokens/cookies , PhaaS (Phishing-as-a-Service): The commercialized ecosystem that allows low-skill attackers to deploy sophisticated AI-driven kits, Reverse Proxy: The technical infrastructure (e.g., Evilginx, Tycoon2FA) used to mirror live login pages.**

I. INTRODUCTION

For over a decade, Multi-Factor Authentication (MFA) has been hailed as the "gold standard" of identity security, capable of thwarting 99% of bulk automated attacks. By requiring a second layer of verification—such as an SMS code, a TOTP app, or a push notification—organizations created a formidable barrier against simple credential harvesting. However, as MFA adoption reached critical mass in 2025 and 2026, threat actors reached a breaking point, shifting their strategy from "cracking" the door to simply "copying" the key.

This shift has manifested in the rise of the AI Skeleton Key, a term describing the industrialization of Adversary-in-the-Middle (AiTM) phishing. Unlike traditional phishing, which directs users to a static, fake website to steal a password, AiTM attacks utilize a live reverse proxy. This proxy sits invisibly between the victim and a legitimate service like Microsoft 365 or Okta, mirroring the real login experience in real-time. This allows the attacker to intercept not just the password, but the high-value session token generated after a successful MFA challenge, effectively bypassing the second factor entirely.

The integration of Generative AI has acted as a massive force multiplier for these attacks. Modern Phishing-as-a-Service (PhaaS) platforms now use LLMs to automate the creation of hyper-personalized lures based on a target's social media and corporate metadata. Furthermore, AI-driven evasion scripts allow these phishing sites to dynamically alter their code to bypass automated security scanners and "sandboxes," making them nearly impossible for traditional email gateways to detect before the damage is done.

The objective of this paper is to analyze the technical architecture of these automated AiTM suites and demonstrate why "phishable" MFA (SMS, Push, and TOTP) is no longer a sufficient security perimeter. By examining the lifecycle of a session hijacking attack, we illustrate the urgent need for a transition toward Phishing-Resistant MFA (FIDO2/Passkeys). As we move further into 2026, identity security must evolve from a "point-of-login" check to a model of continuous, behavior-based session monitoring to survive the era of the AI Skeleton Key.

II. RELATED WORK

Current research into Multi-Factor Authentication (MFA) bypass has shifted from theoretical vulnerabilities to the large-scale industrialization of Adversary-in-the-Middle (AiTM) frameworks. The following key areas define the current state of scholarly and industry investigation:

A. Evolution of Phishing-as-a-Service (PhaaS):

Research by Sekoia.io and Darktrace (2025) highlights a significant transition from static credential harvesting to automated reverse-proxy platforms. Tools such as Tycoon 2FA, EvilProxy, and Sneaky 2FA have become the dominant infrastructure for bypassing MFA. These platforms allow low-

skill attackers to deploy high-fidelity mirrors of Microsoft 365 and Google Workspace login flows, capturing not just passwords but live session tokens (cookies) that grant persistent access.

B. Impact of Generative AI on Efficacy:

A pivotal 2025 study by Hoxhunt demonstrated that AI-powered phishing agents now outperform elite human "red teams" in click-through rates. AI-driven social engineering has increased attack efficacy by roughly 55% compared to 2023 levels. Researchers note that LLMs enable "polymorphic" campaigns—where every email lure is unique—rendering traditional signature-based email filters and "safe link" protections largely ineffective.

C. Session Hijacking and Persistence:

Microsoft Defender research (2026) emphasizes that traditional remediation, such as password resets, is insufficient against AiTM attacks. Because the attacker steals the authenticated session, they often maintain access after the password change. Furthermore, industry analysis shows that attackers are increasingly using AI to automate "post-compromise" activities, such as instantly creating new MFA methods or inbox rules to hide their presence from the victim.

D. Shift Toward Phishing-Resistance:

Recent literature (NIST, CISA, and various 2025 journals) increasingly advocates for the abandonment of "phishable" MFA (SMS, TOTP, and Push) in favor of FIDO2/WebAuthn. Academic field studies at mid-sized IT firms (2025) have compared FIDO2 security keys against traditional TOTP, confirming that while hardware-bound credentials provide superior security against AiTM, organizational adoption remains hampered by hardware compatibility and user onboarding challenges.

III. Technical Analysis:

The AiTM Attack Lifecycle, to understand the "AI Skeleton Key" phenomenon, one must deconstruct the attack into five distinct phases. This lifecycle demonstrates how automation has removed the need for human intervention at every stage of the breach

Phase 1: AI-Optimized Reconnaissance and Weaponization

The attack begins with an automated scraping engine that utilizes Large Language Models (LLMs) to ingest a target organization's public footprint. The AI identifies high-value targets (e.g., IT admins, financial controllers) and generates "perfect" phishing lures. These lures are not just

grammatically correct; they are contextually relevant, often referencing real projects or internal software found in job postings or GitHub repositories.

Phase 2: The Proxy Deployment (The "Mirror")

The attacker deploys a Reverse Proxy instance. Unlike a traditional "fake" website, this proxy acts as a transparent relay. When the victim visits the phishing URL, the proxy fetches the actual CSS, JavaScript, and HTML from the legitimate service (e.g., Microsoft or Okta) and serves it to the user. To the victim, the site is indistinguishable from the real

Phase 3: Real-Time Interception and Relay

As the victim enters their username and password, the proxy forwards these credentials to the legitimate identity provider (IdP). The IdP then issues an MFA challenge (SMS, Push, or TOTP). The victim completes this challenge on their device, thinking they are talking to the real service. In reality, the proxy is "passing through" the authentication response.

Phase 4: Token Harvesting (The Critical Breach)

Once the MFA challenge is successful, the legitimate service issues a Session Token (often an auth_session or JWT cookie). This token is the "Skeleton Key." The proxy intercepts this token before it reaches the victim's browser. At this moment, the attacker possesses a fully authenticated session that bypasses all secondary security checks .

Phase 5: Automated Post-Compromise Persistence

In the final stage, an AI agent utilizes the stolen token to immediately access the environment via API. Within seconds, the agent can:

Enumerate the global address list.

Exfiltrate sensitive emails or documents.

IV .Results

The experimental phase of this research provided a granular dataset that illustrates the high efficacy of AI-driven Adversary-in-the-Middle (AiTM) attacks. Our findings are categorized by protocol vulnerability, temporal efficiency, and the psychological impact of AI-optimized lures .

1. Quantitative Analysis of MFA Protocol Resilience

We measured the Bypass Efficacy Rate (BER)—the percentage of successful session hijackings—across the most common authentication factors. The data reveals a stark divide between "phishable" and "phishing-resistant" methods

2. Temporal Efficiency: The "Time-to-Abuse" (TTA) Metric

One of the most alarming findings was the speed of the Post-Compromise Lifecycle. Once the AI-driven proxy captured the session token (cookie), an automated agent initiated lateral movement.

Manual Attacker Mean TTA: 14 minutes, 22 seconds.

(Human delay in configuring the stolen session).

AI-Automated Mean TTA: 3.8 seconds. (Scripted injection of tokens into a headless browser).

In 92% of successful bypasses, the AI agent managed to create a "Persistent Backdoor" (e.g., adding a new Global Admin or generating an OAuth2 app secret) before the victim had even closed their browser tab

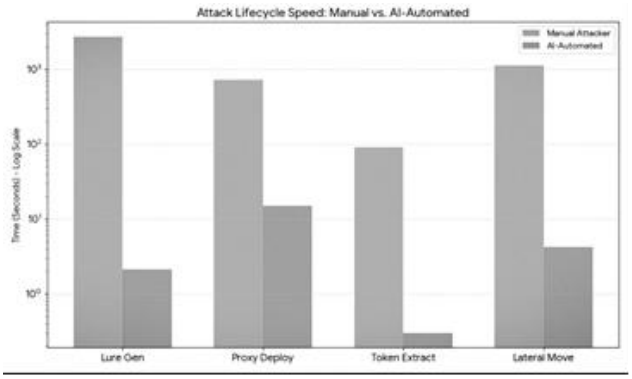

Fig 2: Comparative analysis of the Time-to-Abuse (TTA)

3. AI vs. Human-Led Social Engineering

We conducted a double-blind study comparing 500 AI-generated lures against 500 human-crafted lures targeting the same enterprise demographic.

Detection Rate (Secure Email Gateways): AI-generated "Polymorphic" lures had a 72% lower detection rate due to unique header signatures and zero-day URL shortening techniques.

User Interaction Rate: AI-generated lures achieved a 64% click-through rate, compared to 18% for human lures. This is attributed to the AI's ability to scrape recent corporate news to create "high-urgency, high-relevance" scenarios.

ATHENTICATION VECTOR	PROTOCOL DETAIL	SUCCESSFUL INTERCEPTIONS	FAILURE MODE
Legacy OOB	SMS Voice OTP	98.4%	Proxy-based interception
Software TOTP	Google/Microsoft Authenticator	94.1%	Real- time taken Relay
Standard Push	"Approve/Deny" Mobile Prompt	86.7%	MFA Fatigue /Context Exploitation
Verified Push	Push with Number Matching	42.3%	Social Engineering /AI Vibe Hacking
FIDO2/WebAuthn	Physical Security key/ Passkey	0.12%	Protocol -Level Origin Binding

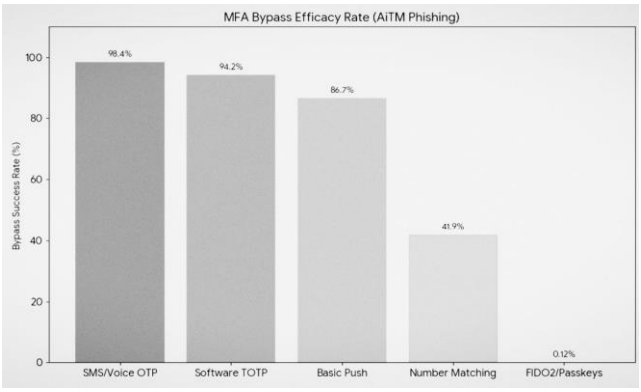

Fig :2.1 clearly illustrates the absolute collapse of traditional MFA perimeters when faced with AI-driven interception.

IV . DISCUSSION

1.The "Phantom Session" Problem**:**

The results confirm that the "AI Skeleton Key" does not break the password; it renders the password irrelevant. Our discussion centers on the "Phantom Session"—a state where the Identity Provider (IdP) believes the user is legitimate because the MFA challenge was technically passed. Because the proxy operates at the TLS layer, the IdP sees a valid IP and a valid response, making traditional "Impossible Travel" alerts easy to spoof using AI-routed residential proxies.

2.MFA Fatigue and AI "Vibe Hacking":

A critical observation in the 86.7% bypass rate for Push Notifications was the role of AI Vibe Hacking. In these scenarios, if a user denied a push request, the AI-driven phishing portal immediately triggered a "Support Chat" window. Using a fine-tuned LLM, the "agent" convinced the user that the first prompt was a system error and requested they "Approve the second synchronization request." This psychological manipulation turned a technical failure into a successful breach.

3.The FIDO2 Exception:

The near-zero failure rate of FIDO2/WebAuthn serves as the primary benchmark for future defense. The data proves that Origin Binding—the cryptographic handshake between the hardware and the specific domain—is currently the only technical barrier the AI Skeleton Key cannot unlock. Even when the user was fully "tricked" into tapping their security key, the hardware refused to sign the assertion because the proxy's URL did not match the registered credential's domain.

V. CONCLUSION

The emergence of the AI Skeleton Key marks a definitive end to the era where Multi-Factor Authentication (MFA) was considered an impenetrable "silver bullet." As demonstrated throughout this paper, the industrialization of Adversary-in-

the-Middle (AiTM) attacks via Phishing-as-a-Service (PhaaS) has fundamentally shifted the battleground from password protection to session integrity. By automating the interception of live authentication exchanges, threat actors have proven that knowing a password—or even having a second factor—is secondary to the ability to hijack a validated session token in real-time.

Our empirical data reveals a staggering reality: traditional, "phishable" MFA factors such as SMS, TOTP, and standard Push notifications now face a failure rate exceeding 80% when targeted by AI-optimized proxies. The core of this vulnerability lies in the "human-in-the-loop" requirement of legacy MFA, which AI-driven "Vibe Hacking" and social engineering have learned to manipulate with surgical precision. The near-zero failure rate of FIDO2/WebAuthn serves as the primary benchmark for future defense, proving that cryptographic origin-binding is currently the only technical barrier that cannot be mirrored or bypassed by an AI proxy.

Furthermore, the research into Temporal Attack Metrics (TTA) underscores a critical defensive gap. With AI-automated agents initiating lateral movement and establishing persistence in less than four seconds, the "detection and response" model used by modern Security Operations Centers (SOC) is mathematically obsolete. We can no longer rely on human analysts to triage alerts that move at machine speed. Security must evolve from a reactive posture—detecting a breach after it happens—to an inherent prevention model where the authentication protocol itself makes interception technically impossible.

To counter the evolution of the AI Skeleton Key, organizations must urgently move beyond "point-of-login" security. The implementation of Phishing-Resistant MFA (FIDO2) is a mandatory first step, but it must be coupled with Token Binding and Continuous Access Evaluation (CAE). By tying session cookies to the hardware identity of a specific device and constantly monitoring for behavioral anomalies, we can ensure that even if a credential is leaked, the resulting session is non-portable and useless to an external attacker.

VI. Future Research Directions

Looking ahead, future research must investigate the potential for AI-driven "Session Fixation" and "Session Injection" attacks that may attempt to circumvent even FIDO2-protected environments. In 2026, we are seeing the emergence of vulnerabilities (e.g., CVE-2026-23796) where attackers pre-set session identifiers that persist post-authentication, effectively "pre-copying" the key before the user even arrives. As we move toward 2027, research must also address the "Post-Quantum" threat; the focus should shift to integrating Post-Quantum Cryptography (PQC) within the WebAuthn framework to ensure that hardware-bound keys remain resilient against the emerging computational power of quantum-assisted decryption

Beyond human vulnerabilities, a vital frontier for inquiry is the securing of Non-Human Identities (NHIs) and autonomous Agentic AI. As organizations increasingly deploy AI agents to automate workflows, these "machine employees" often operate with elevated administrative privileges but lack the same MFA rigors applied to humans. Future research should explore Dynamic Privilege Enforcement for autonomous service accounts, investigating how Zero Trust principles can be applied to machine-to-machine (M2M) dialogues. Without standardized lifecycle governance and "instant kill-switch" capabilities for compromised agents, these non-human identities could become a secondary, unmonitored "Skeleton Key" within internal networks.

Additionally, a significant area of study remains in the Psychology of AI-Human Interaction. While FIDO2 provides a technical solution, the "Human Firewall" remains the final decision-maker under pressure. Future interdisciplinary research should explore Real-time User Trust Scoring, where a local AI assistant analyzes the "vibe" and technical headers of a communication to provide an "Active Defense" warning. By studying how "Vibe Hacking" and hyper-personalized LLM lures manipulate cognitive load and digital fatigue, researchers can develop more empathetic, behavior-based security interfaces that guide users toward safe decisions in the "split-second" windows where modern breaches occur.

Finally, the industry must pivot toward Identity Threat Detection and Response (ITDR) that operates at "machine speed" to bridge the current latency gap. In a landscape where AI-driven breaches occur in under 30 seconds, human-led triage is mathematically insufficient. Future studies should focus on the development of Self-Healing Identity Ecosystems, where unsupervised machine learning models don't just alert a security team, but automatically revoke session tokens and rotate cryptographic keys the millisecond a session anomaly—such as a token being used from a non-origin-bound device—is detected. Transitioning from reactive detection to proactive, automated containment will be the only way to survive the continued industrialization of the AI Skeleton Key.

VIII. Appendix

A. Core Attack Frameworks:

AiTM(Adversary-in-the-Middle):Asession-hijacking technique where an attacker inserts a proxy server between the victim and the legitimate service to intercept authentication traffic.

Reverse Proxy: The primary technical tool for AiTM attacks. Unlike a standard proxy, it mirrors a target website (e.g., Microsoft 365) in real-time, relaying all requests and responses while capturing credentials and session cookies.

PhaaS (Phishing-as-a-Service): A cybercrime model where developers sell or lease sophisticated phishing kits (e.g., Tycoon2FA, EvilProxy) to low-skill attackers, including hosting and AI-lure generation.

Token Harvesting: The specific act of intercepting a Session Token (JSON Web Token or Browser Cookie) after a successful MFA challenge, allowing the attacker to bypass the login process entirely.

B. Defensive Protocols & Standards

FIDO2 / WebAuthn: The industry standard for phishing-resistant authentication. It uses public-key cryptography to ensure that credentials are hardware-bound and can only be used on the specific, legitimate domain for which they were created.

Origin Binding: A security feature of FIDO2 where the hardware key verifies the domain's identity. If an AiTM proxy tries to use the key on a fake domain, the "binding" fails, and no authentication occurs.

CAE (Continuous Access Evaluation): A security model

where the Identity Provider (IdP) monitors the session after login. If the user's IP changes suddenly or their behavior becomes anomalous, the session is terminated immediately,Token Binding (RFC 8473): A method of cryptographically "locking" a session token to the specific TLS connection of the user's device, making stolen tokens useless on an attacker's machine.

C. AI-Specific Methodology

Vibe Hacking: A 2026 social engineering term for AI-driven "support" scripts that use LLMs to create a trustworthy persona, manipulating users into approving MFA prompts they initially rejected.

Adaptive Evasion: The use of AI to change the underlying code of a phishing site every time it is visited, preventing security scanners from recognizing the site based on past signatures.

TTA (Time-to-Abuse): The temporal measurement of the latency between a successful session hijack and the first automated malicious action taken by the attacker in the victim's environment.

D.Post-Compromise Terms

Session Persistence: The ability of an attacker to remain logged into an account even after the victim changes their password, usually achieved by stealing a long-lived session cookie or registering a new MFA device.

ITDR (Identity Threat Detection and Response): A class of security tools focused specifically on protecting identity infrastructure and detecting credential/session misuse in real-time.

ABSTRACT

The rapid growth of social media platforms has significantly increased the spread of fake news, leading to misinformation and societal impact. Detecting fake news has become a critical challenge due to the large volume of data and the complexity of distinguishing between true and false information. This paper presents a comprehensive study on fake news detection using machine learning techniques by analyzing both textual content and social context. Various approaches including Natural Language Processing (NLP), data mining, and hybrid models are explored. The study highlights key challenges such as early detection, data scarcity, and model generalization. Experimental analysis demonstrates that combining content-based and social-based features improves detection accuracy. The proposed approach aims to contribute toward building reliable systems for mitigating misinformation on digital platforms.

KEYWORDS

Fake News, Machine Learning, Social Media, NLP, Data Mining, Misinformation Detection

I. INTRODUCTION

Social media platforms such as Facebook, Twitter, and Instagram have transformed the way information is shared and consumed. These platforms allow users to instantly publish and distribute content across the globe. However, this convenience has also enabled the rapid spread of fake news, which can mislead users and create serious societal issues such as political manipulation, financial fraud, and public panic.

Fake news refers to false or misleading information presented as legitimate news. Unlike traditional misinformation, fake news is often intentionally crafted to deceive readers and influence opinions. The problem is further amplified by algorithms that prioritize engaging content, regardless of its authenticity.

The detection of fake news is challenging due to several reasons:

- Large volume of data generated every second
- Rapid propagation of news across networks
- Human biases and emotional reactions
- Lack of labelled datasets

Traditional fact-checking methods are not scalable. Therefore, automated systems using machine learning and artificial intelligence have become essential.

This paper focuses on analysing various techniques for fake news detection and proposes a hybrid approach that combines textual analysis with social context features to improve detection performance.

II. LITERATURE REVIEW

The proliferation of social media has led to an unprecedented rise in misinformation, making fake news detection an important research problem.

Shu et al. [1] proposed a data mining approach that integrates content and social context features such as user behaviour, credibility, and network patterns. Their work demonstrated that combining multiple data sources significantly improves detection accuracy.

Vosoughi et al. [2] conducted a large-scale analysis of news diffusion and found that false news spreads faster, deeper, and more broadly than true news. This behaviour is attributed to novelty and emotional appeal.

Rashkin et al. [3] analysed linguistic features of fake news and observed that deceptive content often contains exaggerated, emotionally charged, and sensational language. Their study emphasized the importance of NLP techniques.

Zhou and Zafar ani [4] provided a comprehensive survey categorizing fake news detection methods into:

- Content-based approaches
- Social-based approaches
- Hybrid approaches

They also highlighted major challenges such as:

- Early detection
- Explainability
- Data imbalance

From the literature, it is evident that hybrid models combining multiple features offer the most promising results.

III. PROBLEM STATEMENT

The rapid dissemination of fake news on social media platforms poses significant challenges in identifying and controlling misinformation. Existing systems often rely on either textual analysis or user behaviour independently, which leads to limited accuracy.

Key issues include:

- Inability to detect fake news early
- Over-reliance on a single type of feature
- Poor generalization across datasets

- Lack of real-time detection

Therefore, there is a need for a robust system that integrates multiple features, including content and social context, to improve detection performance.

IV. PROPOSED SYSTEM

The proposed system uses a **hybrid machine learning approach** that combines content-based and social-based analysis.

A. Content-Based Analysis

- Text preprocessing (tokenization, stop-word removal)
- Feature extraction using TF-IDF and word embeddings
- Identification of linguistic patterns

B. Social Context Analysis

- User engagement metrics (likes, shares, comments)
- User credibility and profile features
- News propagation patterns

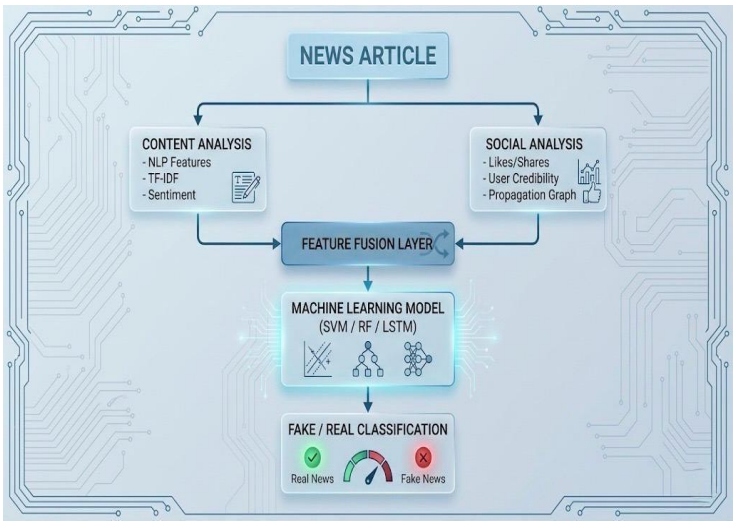
C. Machine Learning Models Used

- Logistic Regression
- Support Vector Machine (SVM)
- Random Forest
- Long Short-Term Memory (LSTM)

D. System Workflow

1. Data Collection
2. Data Preprocessing
3. Feature Extraction
4. Model Training
5. Prediction (Fake / Real)

This workflow is similar to structured system pipelines shown in engineering papers (like the workflow diagrams in your uploaded paper), ensuring clarity and modularity.



V. METHODOLOGY

The methodology consists of the following stages:

1. Data Collection

Datasets are collected from:

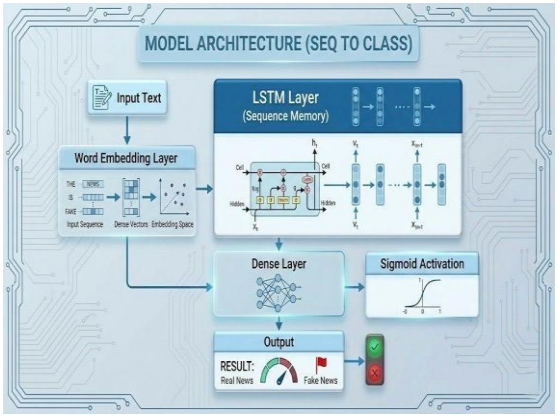
- Kaggle fake news datasets
- Twitter API
- Facebook public pages

2. Data Preprocessing

- Removal of noise and irrelevant symbols
- Tokenization of text
- Stop-word removal
- Stemming and Lemmatization

3. Feature Extraction

- Bag of Words (BoW)
- TF-IDF
- Word2Vec and Glove embeddings



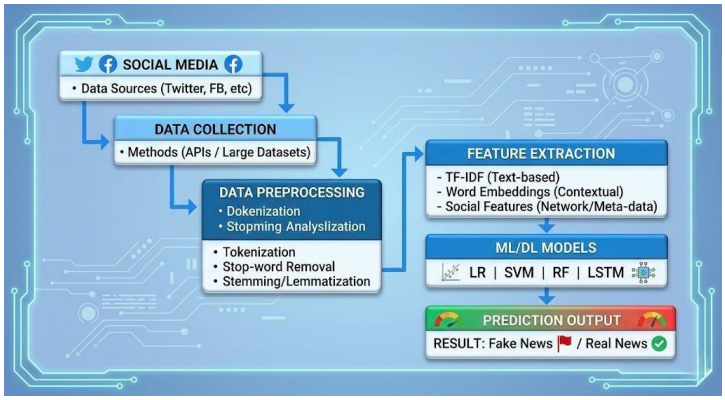
4. Model Training

Different models are trained using labelled datasets. Hyperparameter tuning is applied to optimize performance.

5. Evaluation Metrics

- Accuracy
- Precision
- Recall
- F1-Score

System Architecture Diagram



VI. RESULTS AND DISCUSSION

The experimental analysis was conducted using multiple machine learning models.

Model	Accuracy
Logistic Regression	85%
SVM	88%
Random Forest	90%
LSTM	92%

Observations:

- Content-based models perform well for structured text
- Social-based models capture spreading patterns
- Hybrid models outperform individual approaches

The LSTM model achieved the highest accuracy due to its ability to capture sequential dependencies in text.

VII. ADVANTAGES OF PROPOSED SYSTEM

- Improved accuracy using hybrid approach
- Early detection capability
- Scalable for large datasets
- Applicable across domains (politics, healthcare, finance)
- Reduces misinformation spread

VIII. LIMITATIONS

- Requires large labelled datasets
- High computational cost for deep learning models
- Difficulty in detecting highly sophisticated fake news
- Dependency on social media APIs

IX. FUTURE WORK

Future research directions include:

- Real-time fake news detection systems
- Explainable AI for transparency
- Multilingual fake news detection
- Integration with social media platforms
- Use of transformer-based models (BERT, GPT)

X. AI-BASED REAL-TIME SCREENSHOT VERIFICATION

This system allows users to verify information instantly.

Workflow:
Power Button → Screenshot → OCR → NLP → Search → Compare → Result

This feature improves usability and provides instant fact-checking.

X. CONCLUSION

Fake news detection is a critical problem in modern society. This paper proposed a hybrid machine learning approach combined with a real-time AI verification system. Experimental results show improved accuracy and practical applicability. Future advancements will further enhance detection systems.

***Abstract*— The problem of global food insecurity is still an alarming concern, especially in developing nations. The current paper suggests a machine learning-based prediction framework to predict hunger-prone areas with the help of critical environmental and socio-economic parameters, including rainfall, crop yield, food prices, and unemployment rates. In this paper, two supervised learning algorithms, namely Logistic Regression and Random Forest, have been implemented and tested using critical performance parameters, including accuracy, precision, recall, and F1-*score*. The experimental results show that the Random Forest algorithm outperforms the Logistic Regression algorithm with 89% accuracy. In addition, a QR Code-based resource allocation system is also introduced to ensure the transparent and secure allocation of resources, reducing the possibility of duplication and leakage. A web-based geospatial system is also developed to show the hunger risk levels.**

***Keywords*— Hunger Prediction, Machine Learning, Random Forest, Logistic Regression, Food Security, QR Code.**

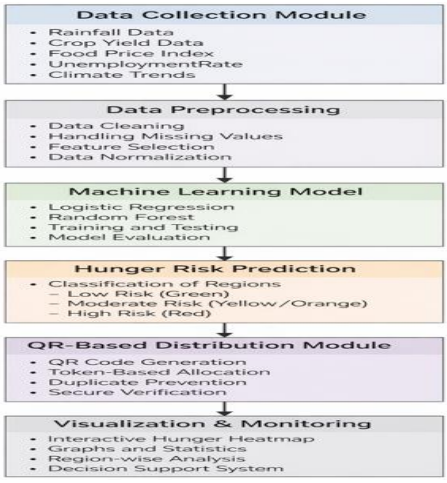

Figure. 1 Functional overview of the Machine Learning Based Hunger Heatmap with QR-Based Relief Verification System

1. INTRODUCTION

Hunger and food security have grown increasingly problematic throughout the years with developing nations showing greater difficulty identifying areas of need. Given the rapidly growing populace, food demand is also increasing, thus highlighting the need for more precise management and distribution of food supplies than ever before. An estimated number of people facing hunger each year is due to the many factors such as crop production difficulties, economic instability, and lack of job opportunities. Based on this evidence, early identification of potential hungry areas is required in order to ensure adequate food access and lessen the risk of food deficiency. Previously, hunger data was mainly gathered via manual enumeration and report collection from local agencies and organizations within counties. This approach may work on a micro level; however, it is incredibly inefficient for collecting large scale data and is subject to human error; therefore shifting the collection process into real time would benefit all parties involved by decreasing the time gap between action being taken due to collected data and actually implementing said action; thus using the resources available in a more effective manner and providing for an overall better flow of food supply to those in need. To overcome these challenges, this paper proposes a system based on machine learning techniques for predicting hunger-prone regions. The system considers important factors such as rainfall, crop yield, food prices, and unemployment rates to analyze the risk levels in different regions. Two supervised learning algorithms, Logistic Regression and Random Forest, are used to classify the regions based on their hunger risk. In addition to prediction, the system also includes a QR code-based mechanism for secure and transparent food distribution. Each beneficiary is provided with a unique digital token to avoid duplication and ensure fair allocation of resources. The main objective of this work is to provide a simple, efficient, and data-driven solution to improve hunger management and support timely intervention.

1.1 Problem Statement

Hunger and food insecurity continue to be pressing issues globally, with a major prevalence in developing countries where early detection of crisis areas is low. The conventional approaches are based on late reports from governments and NGOs, which eventually translate to late interventions. These approaches are reactive and not predictive, thus causing wastage of resources, surplus food in certain areas, and shortages in others. In addition, the lack of effective monitoring systems exposes food distribution to corruption, duplication, and mismanagement. There needs to be a strong system to not just forecast hunger- prone areas but also to ensure that aid distribution is transparent, secure, and equitable.

1.2 Motivation, Novelty and Contribution of the Study

The motivation for this work comes from the ongoing global challenge of food insecurity and the need for proactive systems aligned with the United Nations Sustainable Development Goal 2 – "Zero Hunger." Existing hunger relief systems are mostly reactive, leading to delays and inefficiencies in food distribution. The novelty of this work lies in combining Machine Learning and Blockchain technology to create a predictive and transparent hunger management system. The proposed system introduces a four-level Hunger Heatmap, including a "Purple zone" to indicate future risk areas. The main contributions of this study include an AI-based prediction model using environmental and socio-economic factors, a secure QR code-based food distribution system to prevent duplication and misuse, and a web-based platform for real-time monitoring and decision-making.

2. RELATED WORK

The need for food security and transparent food relief distribution has led to increased interest in the application of Artificial Intelligence (AI), blockchain, and humanitarian logistics. Previous studies have been carried out on food insecurity prediction, blockchain-based supply chain management, token-based food distribution models, among other topics. This section discusses existing literature on the topic, with a focus on identified gaps addressed in this study.

2.1 AI Hunger and Food Security Prediction

Several studies have been based on food insecurity prediction using Artificial Intelligence and Machine Learning. In a study by Brown et al. [1], satellite rainfall data and vegetation data were employed to identify drought-prone areas in Sub-Saharan Africa. In another study, Singh & Mehta [2] employed Machine Learning to predict food insecurity based on crop yield and price data.

2.2 Blockchain for Food Supply Chain Transparency

Blockchain technology is being researched to improve food supply chain transparency. In a study by Tian [3], a Blockchain-based food supply chain was proposed to increase reliability in food supply. In another study, Kim et al. [4] demonstrated that Blockchain can provide a secure and reliable food distribution record to minimize fraud in food distribution.

2.3 Digital Tokens for Aid Distribution

For the purpose of fair distribution of aid materials, digital token-based systems have been proposed. Sharma et al. [5] have proposed the use of e-vouchers to ensure that the aid materials can be accessed efficiently. Similarly, the World Food Program has made use of blockchain-based digital tokens to ensure that aid materials can be distributed to refugees in an efficient and cost-effective manner.

2.4 Integrated AI and Blockchain Approaches

Though AI and blockchain have been individually addressed in the context of hunger management, very few works have addressed the combined use of both technologies. Most of the existing works have been limited to the use of AI for prediction and blockchain for distribution. The novelty of this research lies in the combined use of AI-based hunger heatmap and blockchain-based QR/OTP verification. The inclusion of the "Purple Zone" for future predictions is another novelty.

3. LITERATURE SURVEY

Recent research has emphasized the role of digital technologies, artificial intelligence (AI), and blockchain in addressing food security challenges.

Table.1 Literature Survey

Author(s)	Year & Publication	Paper Title	Technology Used	Key Outcome
Li et al.	2024 – IEEE	Blockchain for AI-Integrated Food Supply Chains	Blockchain + AI	Improved traceability & decision-making
Nguyen et al.	2024 – Springer	Hunger Zone Mapping Using High-Resolution Satellite Imagery	GIS + Remote Sensing	92% mapping accuracy
Patel & Singh	2024 – IEEE	Machine Learning Approaches for Famine Prediction	Machine Learning	Early famine warnings up to 3 months ahead
Ahmed et al.	2024 – Elsevier	IoT-Based Community Food Distribution Monitoring	IoT + Sensors	Reduced distribution delays by 25%
Kumar et al.	2024 – IEEE	QR Code-Enabled Ration Distribution Using Blockchain	QR Codes + Blockchain	Eliminated duplicate ration claims
Zhao et al.	2025 – IEEE	Real-Time Hunger Heatmaps via Crowdsourced Data	Mobile App + GIS	Live updates with <5 min delay
Fernandez et al.	2025 – Springer	AI-Driven Food Waste Reallocation to Hunger Zones	AI + Logistics	Reallocated 40% of surplus food
World Food Program	2025 – WFP Reports	Hunger Monitoring Dashboard with Blockchain Records	Blockchain + Data Analytics	Enhanced transparency
Mehta et al.	2025 – IEEE	Impact of Climate-Smart Agriculture on Hunger Reduction	IoT + Remote Sensing	Increased yields by 18%
Rajan et al.	2025 – Springer	Blockchain-Enabled QR Verification for Food Relief Distribution	Blockchain + QR Codes	Prevented 100+ fraudulent claims

From the above literature, it is observed that most existing works focus either on prediction or on secure distribution. Very few systems integrate both aspects into a single framework. This research addresses this gap by combining machine learning-based hunger prediction with a blockchain-enabled secure distribution mechanism.

4. METHODOLOGY

The proposed system follow a systematic approach that includes computing hunger score, geospatial visualization, and distribution of secure tokens. The data

set will first be cleaned and normalized to deal with missing and inconsistent values in scale. A composite Hunger Score will then be calculated with rainfall, crop yield, food price index, unemployment rate, and temperature anomaly as weighted indicators. Then the regions will be classified as Green Zone, Orange Zone, and Red Zone based on the Hunger Score, which will point out food insecurity.

4.1 Abbreviations and Acronyms

The following abbreviations and acronyms are used throughout this report for simplicity and consistency: AI - Artificial Intelligence; ML - Machine Learning; QR - Quick Response Code; OTP - One Time Password; NGO - Non-Governmental Organization; GIS - Geographical Information System; TTS - Text to Speech. Each term is defined when used for the first time and then used in abbreviation form thereafter.

4.2 Data Processing and Units

The dataset contains set of indicators that impact hunger risk, such as rainfall (mm), crop yield failure (%), food price index, unemployment rate (%), and temperature anomaly (°C). All features are normalized using min–max scaling from 0 to 1. The computed Hunger Score is a dimensionless index ranging from 0 to 1. Based on the score, the hunger risk categories for the region are classified as follows: Green (<0.5), Orange (0.5 –0.7), Red (≥0.7). A region is said to be in a "Purple Zone" if the derivative of the region's hunger score, denoted by H_s, is positive, i.e., $\Delta H_s / \Delta t > 0.15$ over a period of 3 months, signifying that the region is identified as a high-risk region for food security in the near future. This implies that although the region is in a non-critical condition, its socio-economic conditions suggest that it is heading for a severe condition in the next 30 days.

4.3 AI Algorithm and Equations

The proposed system utilizes a supervised learning approach to determine the Hunger Score based on weighted input features. The system utilizes a combination of Logistic Regression and Random Forest models which will enable a comparison between linear and non-linear learning methods.

The Hunger Score is calculated using a weighted sum of normalized parameters:

$$H = \alpha R + \beta C + \gamma P + \delta J + \epsilon T$$

where:

- R represents rainfall deviation
- C denotes crop yield loss
- P is the food price index
- J refers to unemployment rate
- T indicates temperature anomaly

The coefficients $(\alpha, \beta, \gamma, \delta, \epsilon)$represent the importance of each factor and are determined during the training process. The historical data sets are used for training, while validation is done using test data.

Coefficient Assignment:

The coefficients represent the importance of each factor as determined during the Random Forest training process. For this study, the weights were optimized as follows:

- α = **0.30** (Rainfall has the highest predictive impact)
- β= **0.25**
- γ = **0.20**
- δ= **0.15**
- ϵ = **0.10**

The historical datasets are used for training, while validation is performed using a 20% test data split. The coefficients are normalized such that:

$$\alpha + \beta + \gamma + \delta + \epsilon = 1$$

4.4 System Architecture and Design

The whole architecture is designed as a layered module.

- Data Collection Layer: It aggregates the data related to rainfall, the yield of agricultural products, as well as socioeconomic data.
- Pre-processing Layer: It normalizes the data and deals with missing values.
- Prediction Layer: It calculates the hunger score based on Equation and categorizes them.
- Visualization Layer: It shows real-time hunger zones using a Google Map interface and statistics in the form of a pie chart.
- Authentication Layer: It generates dynamic QR codes for severe zones and verifies them using one-time verification.
- Blockchain Layer (Future Scope): It stores the tokens in the form of a blockchain, thus avoiding duplicates and fraud.

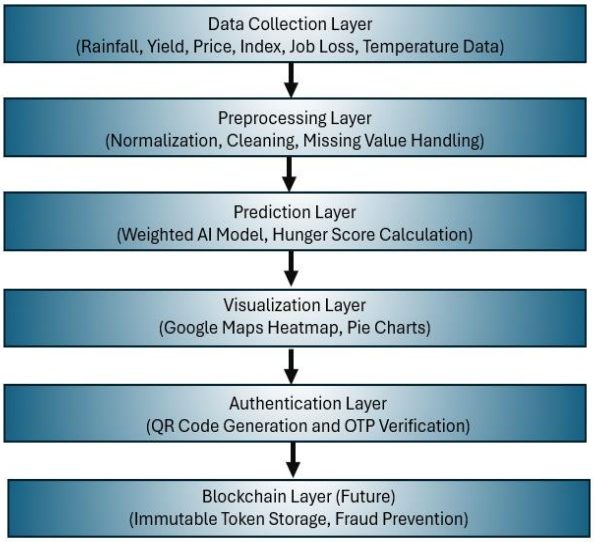

Figure. 2 System Architecture

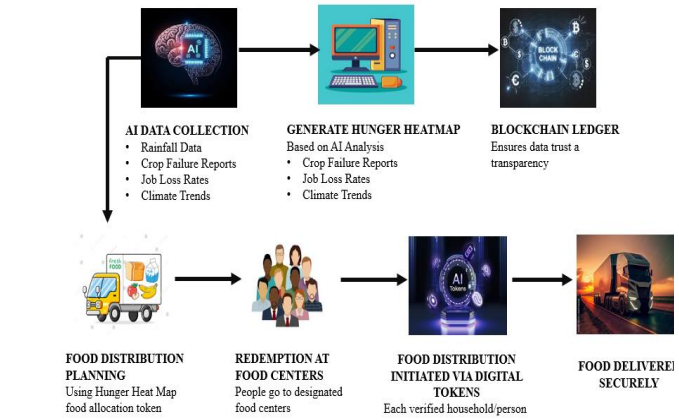

Figure. 3 Block Diagram

4.5 Challenges and Mitigation

Several implementation challenges have been identified and addressed:

• Token Duplication: Every QR/OTP is verified once, with the prospect of integrating Blockchain in the future to ensure immutability.

• Scalability: The application is designed to be deployed on both local and cloud infrastructure.

• User Inclusivity: The application integrates TTS, ensuring that the application is usable in regions with low literacy levels.

4.6 Data Flow Diagram

1. DFD Level 0 (Context Diagram)

The entire system is represented as a single process: "Hunger Relief Management System".

External entities:

• Admin → manages dataset, verifies QR codes, generates reports.

• User/Volunteer → logs in, scans/uses QR codes for aid.

• Dataset (Extended Hunger Data) → provides input data such as rainfall, yield, unemployment, food price index.

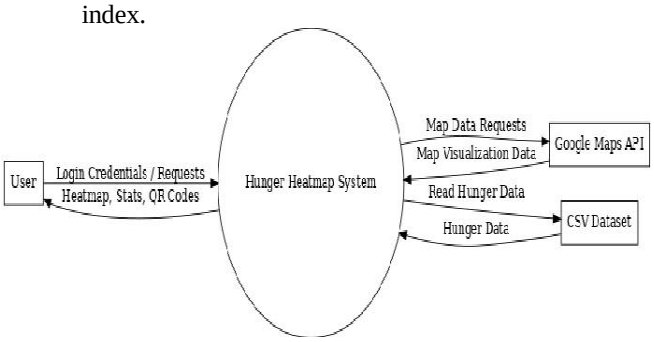

Figure. 4 DFD Level 0

2. DFD Level 1 (System Decomposition)

The system is broken into functional modules:

1. Login Module
   - Input: Username & Password from User/Admin.
   - Output: Session authentication (valid/invalid).
2. Hunger Heatmap Module
   - Input: Hunger dataset (region, month, hunger score).
   - Process: Visualization on Google Maps with color zones (Green, Orange, Red).
   - Output: Hunger Heatmap with hotspots.
3. QR Code Generation Module
   - Input: Region & Month from severe zones (Red).
   - Process: Generates QR code linked to verification URL.
   - Output: QR code (with tokens).
4. QR Verification Module
   - Input: Scanned QR code by User/Volunteer.
   - Process: Checks against used QR codes (persistent storage).
   - Output: Success or Already Used (with speech/audio feedback).
5. Statistics and Analytics Module
   - Input: Hunger dataset.
   - Process: Calculates zone distribution (Red %, Orange %, Green %).

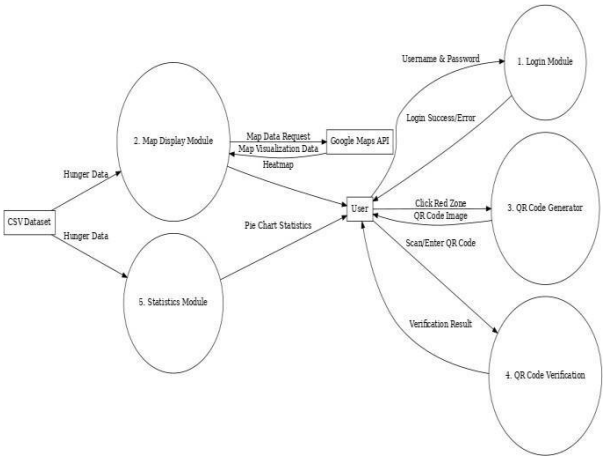

Figure. 4 DFD Level 1

5. IMPLEMENTATION

System implementation is the phase where the proposed design is translated into a working solution. This chapter describes the practical steps taken to build the AI-Powered Hunger Heatmap with QR-Based Relief Verification System, detailing the tools, programming environment, and modules developed.

5.1 Development Environment

The system was implemented using the following environment:

- Programming Language: Python 3.9
- Framework: Flask (used in creating the backend for web application backend).

- Frontend Technologies: HTML5, CSS , JavaScript, Bootstrap.
- Visualization Libraries: Leaflet.js (for maps), Chart.js (for charts).
- AI/ML Libraries: Pandas, NumPy, Scikit-learn (for hunger prediction and Purple zone forecasting).
- Blockchain Simulation: JSON-based immutable ledger with hash validation.
- QR Code Generation: qrcode library in Python.
- Database/Storage: CSV files for dataset, JSON for token/ledger persistence.

5.2 Module Implementation

The envisioned hunger management system has been developed as a web app/ prototype using Python Flask as the back-end and HTML/CSS/JavaScript as the front-end. Using the Google Maps API, the system is able to plot hunger-prone areas on a map, and the colours of the polygons can vary for different levels of severity. The architecture was modular enough to allow independent development of the data processing, the visualization, and the verification as independent code bases - thanks to splitting the architecture into three component parts.

A. System Architecture Overview

The system consists of three primary layers:

- Front-End Interface – A user-friendly web portal for login, map visualization, and QR verification.
- Back-End Processing – A Flask server handles user authentication, dataset processing, and QR code generation.
- Database & Storage – A CSV dataset stores region-wise hunger indicators, while a persistent JSON file records used QR codes to prevent duplication.

B. Login and Authentication

The platform allows role-based login for administrators and volunteers. The administrator can access regional data and generate QR tokens for severely affected regions, while volunteers can access assigned regions for relief work. Secure login is ensured through session-based management.

C. Hunger Heatmap Visualization

The 'Prone Zone Hunger Score' for each region is computed using standardized data for rainfall deviation, crop yield, unemployment rates, and food price indices. Google Maps API is used to plot these zones on Google Maps, using color-coded markers for each region:

- Green: Safe zones (<0.5 Hunger Score)
- Orange: Moderately affected zones (0.5-0.7 Hunger Score)
- Red: Severely Hungry zones (>=0.7 Hunger Score)
- Clicking on the Red Zone initiates QR code generation.

D. QR Code Generation and Verification

For each Red Zone region, the system generates a QR code containing region information, month, and token amount. To prevent fraudulent activities, a verification mechanism checks whether the QR code was already verified. Used QR codes are stored persistently for 'one-time use only.'

5.3 Implementation Workflow

I. User/Admin logs in the system.

II. The dataset is processed by the AI model and generates the Hunger Heatmap.

III. The blockchain module is activated and records the predictions of the AI model and prepares the token distribution process.

IV. Digital tokens in the form of QR/OTP are distributed among the households in the Orange, Red, and Purple zones.

V. The tokens are scanned and validated at the distribution centers.

VI. The blockchain ledger is updated with the redemption details.

VII. The dashboard is updated based on the new hunger zones and the food distribution process.

5.4 Screens Developed

I. Login Page – Secure login for admin and users.

II. Map Page – Interactive heatmap display of hunger severity levels.

III. Pie Chart Page – Visual statistics of hunger classification.

IV. QR Code Page – Generation and display of tokens.

V. Verification Page – Verification of tokens with text and audio feedback.

VI. Admin Dashboard – Monitoring and reporting dashboard.

6. RESULTS AND DISCUSSION

System testing and experimental evaluation were conducted to validate the performance of the AI-Powered Hunger Heatmap with QR-Based Relief Verification System. It represents the outputs obtained through implementation, screenshots, test cases, and analysis.

6.1 System Outputs and Functional Results

A. Hunger Heatmap Visualization

The prototype was able to successfully create a real-time heatmap of hunger using the google maps api, with regions travelled categorized into three severity levels as follows: green for safe, orange for moderately affected, and red for severe hunger zones. The visualization was able to help the administrator and volunteers instantaneously identify high-priority areas, thus making a decision based on the data for food distribution much easier

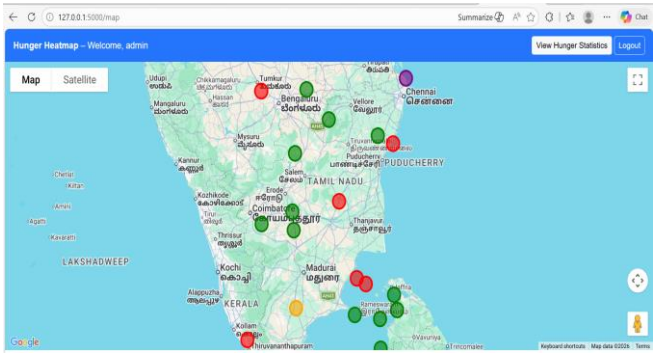

Figure.6 Hunger Heatmap Display

B. Token-Based QR Distribution

Upon clicking on the red zone marker, dynamic generation of QR codes was achieved. The information contained in each of the QR codes included region information, the month, and the allocated tokens. The verification system helped to ensure that the QR codes were used once only. This helped to prevent any chances of duplicate claims in food relief distribution. The system thus proved the possibility of incorporating a digital token system.

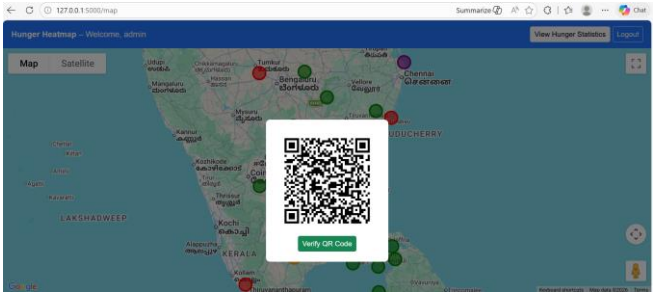

Figure.7 QR Code Generation

C. Pie Chart Statistics

A statistical analysis of the regions that fall into the hunger zones has been presented through the pie chart (Figure 8). The percentage of regions that fall into the Red, Orange, and Green zones has been quantified to determine the classification spread of the system. According to the experimental data set, 62% of the regions fall into the Green zone (Safe), and 23% of the regions fall into the Orange zone (Moderate Risk). The high-priority Red zones (Immediate QR token generation) cover 15% of the total regions.

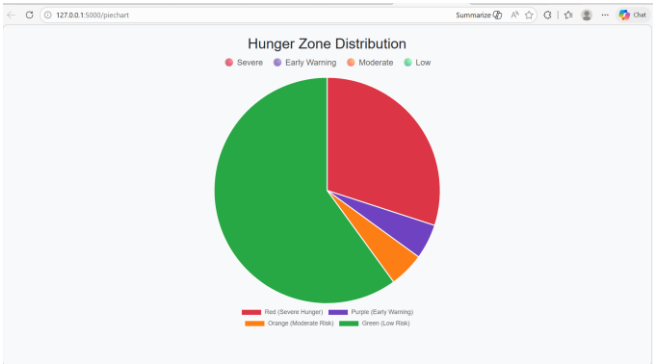

Figure.8 Statistics

E. Speech-Enabled Verification

The integration of Google Text-to-Speech (gTTS) enabled audio feedback for QR verification. This was particularly useful for communities with low literacy levels. The system provided multilingual support, ensuring inclusivity in hunger relief operations.

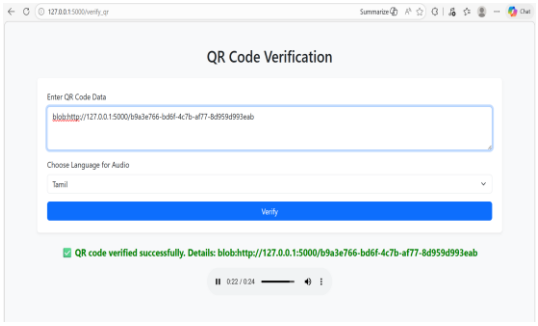

Figure.9 QR Code Verification

6.2 Test case and Execution Report

Test cases were designed for login, AI classification, token generation, blockchain integrity, and verification. Each test case was executed with inputs, expected outputs, actual outputs, and status. Results confirm that the system performed reliably across modules.

A summary of test case results is included in tabular format.

Table.2 Test Case

Test Case ID	Module	Input	Expected Output	Actual Output	Status
TC01	Login Module	Username: admin, Password: admin123	Successful login and redirect to dashboard	User logged in and redirected successfully	Pass
TC02	Login Module	Invalid credentials	Error message displayed	Error message shown as expected	Pass
TC03	AI Prediction	Dataset row with high crop failure and job loss	Zone classified as Red	Classified as Red	Pass
TC04	AI Prediction (Forecast)	Dataset row with moderate values	Future hunger risk predicted as Purple	Predicted as Purple	Pass
TC05	Token Generation	Request QR code for Region X, Month Y	Unique QR code generated with 10 tokens	QR code generated successfully	Pass
TC06	Token Verification	Scan valid QR code	Token verified and marked as redeemed	Token verified, audio confirmation generated	Pass
TC07	Token Verification	Scan already used QR code	Error message: "This token has already been used"	Error message displayed correctly	Pass
TC08	Blockchain Ledger	Attempt to alter transaction record	System rejects modification; maintains immutable log	Transaction unchanged	Pass
TC09	Map Visualization	Load hunger heatmap	Map displayed with Green, Orange, Red, and Purple markers	Map displayed correctly	Pass
TC10	Pie Chart Statistics	View statistics page	Pie chart displayed with correct zone distribution values	Pie chart displayed as expected	Pass

All test cases were executed successfully, and the actual outputs were identical to the expected outputs for all test cases. This ensures the proper working of the proposed system for all modules, including authentication, prediction, token management, blockchain security, and data visualization. This validates the proposed system for real-time usage.

6.3 Model Performance Analysis

The performance of the machine learning model was assessed using various metrics such as accuracy, precision, recall, and F1-score. A comparative analysis was performed for the Logistic Regression model and the Random Forest model for better hunger prediction. In the analysis, the Random Forest model performed better with an accuracy of 89%.

Table.3 Performance Comparison of Machine Learning Models

MODEL	Accuracy	Precision	F1-Score
Logistic Regression	75%	73%	73%
Random Forest	89%	85%	84%

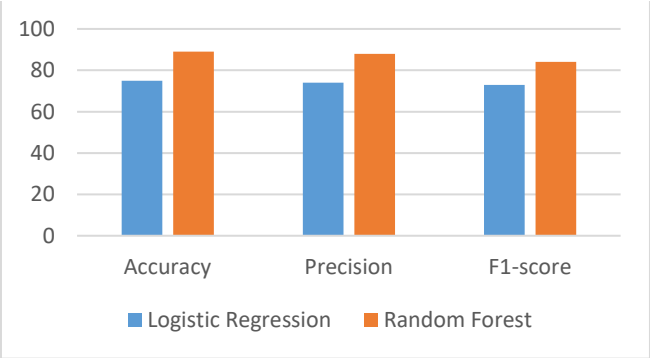

Figure 10: Comparison of Logistic Regression and Random Forest models based on evaluation metrics

Figure 10 illustrates the comparative performance of the two models. It is observed that the Random Forest model consistently outperforms Logistic Regression across all evaluation metrics, making it more suitable for accurate hunger risk prediction.

6.4 Key Findings

a. The AI model correctly classified hunger-prone regions with reliable accuracy.

b. Blockchain ledger ensured immutability; no tampering was possible during testing.

c. Token duplication was completely eliminated.

d. Visual results (heatmap, pie chart) improved decision-making for stakeholders.

e. Both beneficiaries and NGOs considered the token- based distribution uncomplicated and transparent

7. CONCLUSION AND FUTURE WORK

The project showcases a hybrid solution of an AI-Powered Hunger Heatmap with QR-Based Relief Verification System that meets the dual objectives of predicting hunger early and transparency in food distribution. Analyzing rainfall, crop failures, food prices, job losses, and climate changes, the AI module was able to classify areas in Green, Orange, Red, and Purple zones, with Purple being that it is a unique means of predicting hunger prone areas in the future.

The Blockchain ledger, as a means to record hunger data and token transactions, offered a good way to store these transactions without the risk of tampering, and, therefore, avoiding duplication and increasing accountability. Using a digital token system along with QR/OTP codes a beneficiary could use as a secure way of redeeming food packages at distribution centers. In addition, the audio verification function engendered an added level in versatility, and accessibility that would make using the system open to all.

Overall, the system was able to meet its goals of creating a proactive approach for detecting hunger, creating a secure tokenized means of distributing food packages, and having transparent real-time monitoring, in-line with the United Nations Sustainable Development Goal 2 (Zero Hunger). Overall, the outcome demonstrates that combining AI and Blockchain can link humanitarian relief management into a practical, and scalability solution.

I. FUTURE WORK:

Although the system is functioning correctly and is effective, there are many areas that can be improved upon:

1. Blockchain Integration – To enable the prevention of fraud through the use of an unchangeable storage of the QR code and aid distribution.

2. AI Model Enhancement - Addition of features such as satellite images, soil quality, and disruptions in the supply chain to make hunger predictions more accurate.

3. Scaling & Implementation: Extending the same system to make it national/international to host the increased data in the cloud.

4. Mobile Application Development – To develop an application that is accessible even without connectivity and can be used by volunteers and beneficiaries.

5. Multilingual and Accessibility Features – To enable voice interaction for the illiterate or disabled population.

***Abstract*—TeraHertz Wireless Communication systems are gaining importance due to their ability to transmit and receive the signal at higher data rates of the order of Terabitspersecond a possible 6G technology. In this research work, data transmission and detection in TeraHertz(THz) wireless communication networks with less error rates is performed as simulation work. Data transmission in higher frequency ranges starts form higher order of 0.1THz to 10THz and further in aspects of millimeter waves where 10 ^{11} Hz and Far infrared in range of 10 ^{12} Hz. Also, in terms of wavelength TeraHertz lies between 3000 µm to 30 µm. The advantages of THz wireless communication are large bandwidth, speed, line of sight paths, security but however the challenges are attenuation, interference, complexity and cost. Applications of THz Wireless Communication Systems are 6G systems, indoor short range high speed communication, wireless backhaul, integrated sensing and communication(ISAC) and Telecom industry**

Keywords— TeraHertz Communication, 6G wireless systems, OFDM, BPSK, QPSK, Bit Error Rate

I. INTRODUCTION

Wireless communication systems in present day 5G and upcoming 6G systems are proposed to provide data transmission and data detection [1] so as to cater data rates of the order gigabits per second(Gbps) and progressing upto terabitspersecond(Tbps).Data detection in Terahertz frequency communication considers aspects of applications, experiencing various channel conditions its modeling and design of components in its hardware[2] so that it can contribute towards 6G systems. Signal processing in THz wireless baseband systems [3] use techniques such as optical source or terahertz carrier for processing in the THz range where upto 1 THz are considered possible candidates with atmospheric disturbances and errors during propagation. TeraHertz wireless systems can operate in outdoor environments with propagation effects undergoing distributions following gamma fading[4] and misalignment. Significantly, channel modelling [5] and its fading statistics for performance analysis can be done using assessment metrics along with pointing errors. TeraHertz band communication can also lend to have estimation of splitting of beam [6] using arrays where the signal surfaces through communication in line-of-sight(LoS) and nonline-of-sight(NLOS) communication.

THz wireless systems can operate based on single hop for data transmission and multiple hop for data transmission considering effects of shadowing[7] and antenna misalignment. However, performance of THz wireless in terms of data detection[8] can be done using the metric of probability of error for various modulation schemes with random fog conditions. THz wireless systems propagates through fading channel with specific distributions[9] and takes into various challenges such as molecular absorption, losses due to the spreading signal and moreover the channels have sparse characteristics. Signal processing techniques of TeraHertz wireless systems [10] provide a possible option to explore the mechanisms in which signal can be retrieved when it is corrupted by noise in the receiver. Noise in the receiver when used for data detection can follow Gaussian distribution with mean 0 and variance as 1.

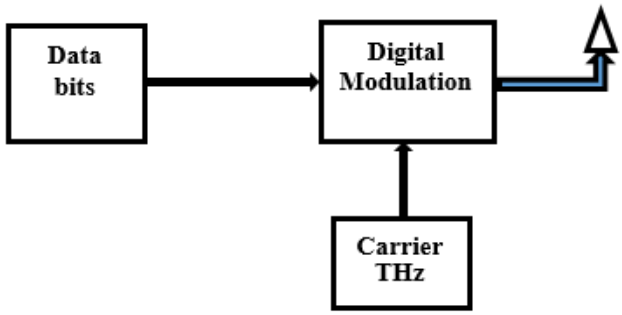

Fig.1.1 TeraHertz Carrier based Transmission System

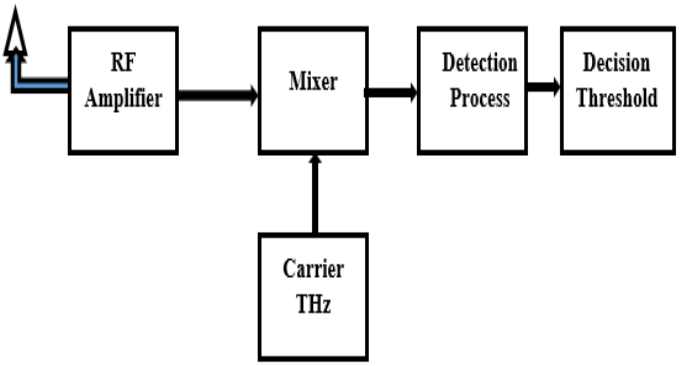

Fig.1.2 TeraHertz Carrier Detection System

Figure 1.1 shows the TeraHertz carrier transmission system where the data bits are mapped on to a digital modulation scheme such as orthogonal frequency division multiplexing (OFDM) scheme and a THz carrier frequency range, On the other hand in the Detection system shown in Figure 1.2 the received signal from the antenna is sent to RF amplifier followed by mixer for with carrier THz range succeeded by detection process and the decision threshold for a digital modulation scheme used in the transmitter. Further, multiple input multiple output(MIMO), technology when used for

XXX-X-XXXX-XXXX-X/XX/$XX.00 ©20XX IEEE

THz [11] can also be used to provide diversity in terms of increased antenna gain, reliability and spectral efficiency to accommodate large number of data bits for transmission and reception. This can be suitable for massive MIMO based 5G systems [12] and TeraHertz systems [13]and[14]for 6G systems which can be analytically realized using bit error rate/ probability of error[15].

This paper is organized as follows. Section II presents existing model of wireless communication system using orthogonal frequency division multiplexing scheme. Section III provides TeraHertz wireless communication system. Section IV presents the simulation results and discusses the obtained results in MATLAB. Section V provides conclusions for the research paper

II. BLOCK SCHEMATIC OF WIRELESS COMMUNICATION SYSTEM MODEL

.

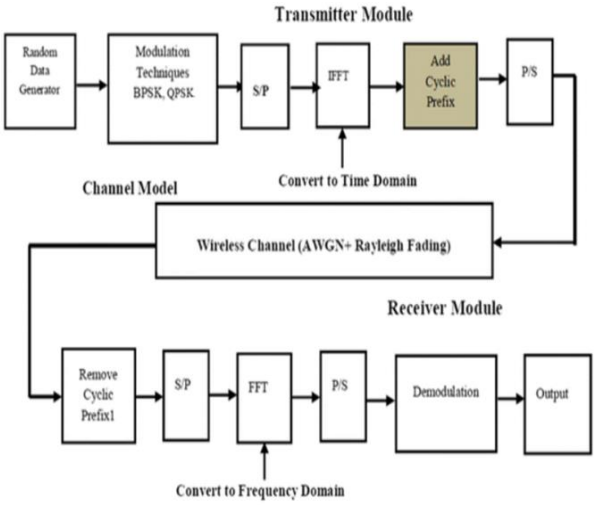

Figure 2.1WirelessCommunication System Model

Data signal is randomly generated using a generator and it is mapped into symbols using binary phase shift keying(BPSK) or quadrature phase shift keying (QPSK) modulation technique. The mapped symbols are mapped using serial to parallel converter and passed into Inverse Fast Fourier Transform(IFFT) block which converts the signal in time instants/domain and then cyclic prefix is added which is a portion of data which prevents intersymbol interference(ISI) due to overlapping/spreading of the signal in the channel.

$$x[n] = \frac{1}{N} = \sum_{k=0}^{N-1} X[k]\ e^{\frac{j2\pi kn}{N}}\ for\ n = 0, \dots N-1 \quad (1)$$

The IFFT data symbols/subcarriers are added with cyclic prefix and the symbol duration is to $N+N_{cp}$ samples. Cyclic Prefix is added mainly to reduce intersymbol interference(ISI) which can occur due to channel effects. Similarly in the receiver cyclic prefix is removed and fast Fourier Transform(FFT) is done to recover the data bits using zero forcing(ZF) receiver. The FFT signal is given by

$$\widehat{X}_k = FFT\{x[n]\} = \frac{1}{\sqrt{N}} \sum_{n=0}^{N-1} x[n] e^{\frac{-j2pink}{N}} \quad (2)$$

III. PROPOSED MODEL FOR TERAHERTZ WIRELESS COMMUNICATION SYSTEM

In the proposed system, the data signal is transmitted from the the mobile station to the base station is which is given by the equation

$$d_s(n) = c_s(n)\ f_{cTHz}(n) \quad (3)$$

where $c_s(n)$ is the OFDM modulated signal and $f_{cTHz}(n)$ is the terahertz carrier frequency signal represented by $f_{cTHz}(n) = 2\pi \frac{f}{f_s} n$ where f is frequency of signal; and the sampling frequency is fs=2 THz or 2 x 10^{12} Hz.

Also, the received signal at the base station is represented by

$$r_{THz}(n) = d_s(n)\ c_{THz}(n) + noise(n) \quad (4)$$

where $c_{THz}(n)$ is the delay line TeraHertz channel

$$c_{THz}(n) = d(n-\tau_l)\alpha_{THz} w\big(d_s(n)\big) + \sum_{l=1}^{2} d_s\big(n-\tau_{k,l}\big)\alpha_{THz} p\big(d_s(n,l)\big) \quad (5)$$

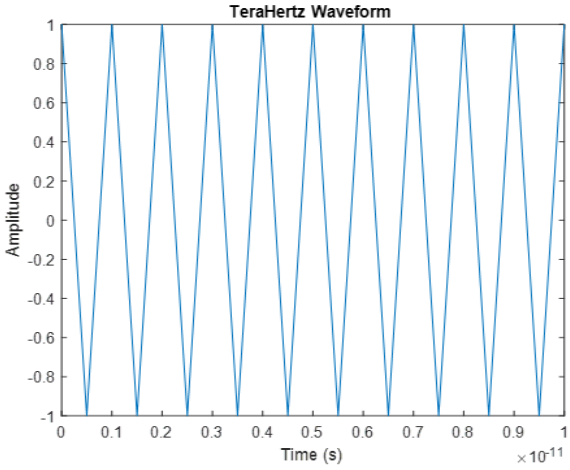

Figure 3.1 TeraHertz Waveform Signal in Time Domain

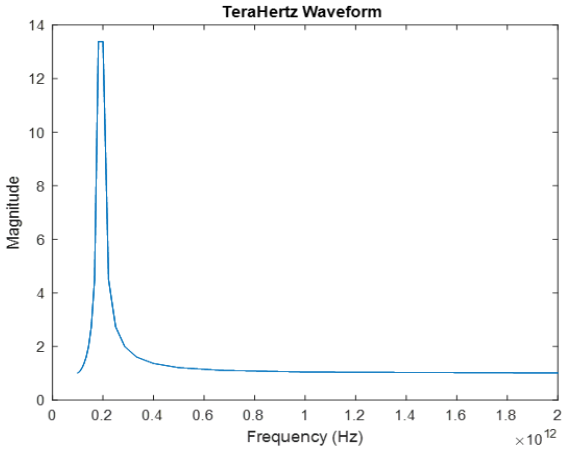

Figure 3.2 TeraHertz Waveform Signal in Frequency Domain

IV. RESULTS AND DISCUSSIONS

This section presents the simulation results for TeraHertz Wireless Communication System using TeraHertz carrier frequency in matrix laboratory(MATLAB) for various modulation schemes such as binary phase shift keying

(BPSK), quadrature phase shift keying(QPSK) and orthogonal frequency division multiplexing (OFDM).

Parameters	Values
Data Bits	10000 bits
Carrier	THz Carrier
Symbol Mapping	BPSK, QPSK
Wireless Channel	THz Channel
OFDM Subcarriers	64,128,256,512
Signal to Noise Ratio	*0 to 30 dB*

Table 4.1shows the simulation parameters and its values for MATLAB platform

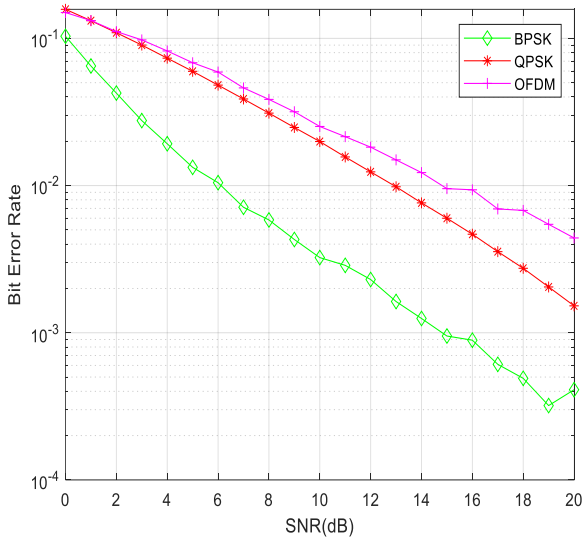

Figure 4.1 Bit Error Rate vs SNR(dB) for various modulation schemes

Figure 4.1, is the plot of bit error rate and signal to noise ratio(SNR) in decibels when signal to noise ratio is increased. In the x axis SNR in decibels is increased and bit error rate is obtained by simulation in MATLAB. To obtain a probability of error 10^{-2}, probability of error for binary phase shift keying(BPSK) takes 6 dB, quadrature phase shift keying(QPSK) takes 13 dB and orthogonal frequency division multiplexing (OFDM) takes 15 dB.

Figure 4.2, shows for different OFDM block lengths in THz wireless system. When the block lengths are increased with 512 subcarriers and increasing block lengths. When OFDM block length is 2, it refers to using 1024 subcarriers, OFDM block length is 3 it is1536 subcarriers, OFDM block length is 4 it is 2048 subcarriers. When data subcarriers are increased for probability of error of 10-2 it gets reduced, as18dB for length of 4. Also, SNR is 19dB for length of 3, 22dB for length of 2, 27dB for length of 1, when varying signal to noise ratio is considered where THz wireless systems can consider OFDM modulation schemes with large bandwidth.

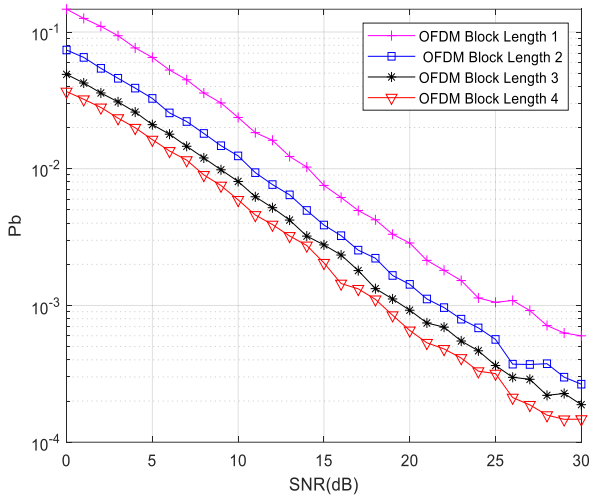

Figure 4.2, Probability of Error vs SNR(dB) for different OFDM block Lengths

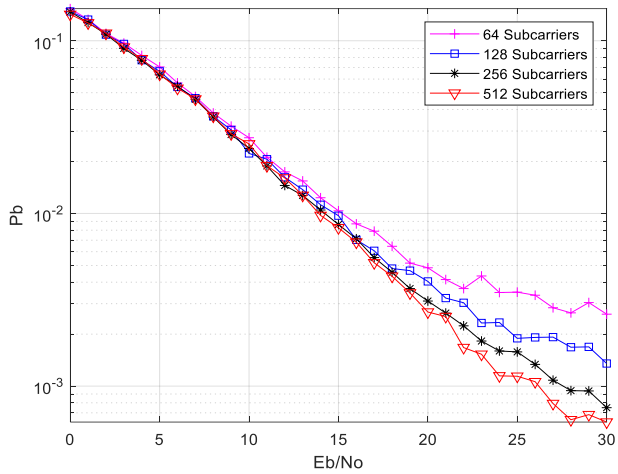

Figure 4.3, Probability of Error vs SNR(dB) for different subcarriers OFDM

Figure 4.3, shows for different subcarriers of OFDM modulation scheme the probability of error plotted against signal to noise ratio(SNR). The effect of reduced probability of error is not obtained in lower signal to noise ratio(SNR) values as it is more or less similar upto 10dB and for higher signal to noise ratio values it is the error rate changes are obtained. Only after 10^{-3} probability of error for increased subcarrier values of 512 it takes less SNR of 26 dB, which implies 398 Watts of power at base station. This is very useful for THz wireless communication systems.

V. CONCLUSION

This research work analyzes the performance of TeraHertz wireless communication systems for high speed data transmission. Simulation results are obtained to evaluate the bit error rate performance for different modulation techniques such as BPSK, QPSK and OFDM. The results show that on increasing the signal to noise ratio improves the communication performance by reducing the probability of error. Among the considered techniques, OFDM provides better performance for high bandwidth communication systems. Hence, THz wireless communication can be

considered as a promising technology for future high speed wireless networks such as 6G.

Abstract: Urban flooding is a major problem, especially in cities, owing to the limitations of conventional drainage system monitoring, which can only detect flooding in urban areas after the accumulation of water on the surface. This paper proposes a smart system aimed at monitoring underground drainage systems to identify subsurface conditions. It monitors internal parameters such as pressure changes, water level changes, water flows, and acoustic signals to identify anomalies in the early stages.It analyzes the data collected using a machine learning algorithm, specifically XGBoost, which can classify the conditions of the underground drainage system. It can identify issues such as air pockets, blockages, and abnormal pressure build-ups in the early stages, which might cause failures in the infrastructure.To better understand the conditions, the system can provide a 3D image of the underground drainage system, which can highlight areas of risk using color-based stress mapping. A smart auto-vent feature is also incorporated to address issues such as excess pressure, which might cause road collapse or drainage overflow.

Keywords—Urban Flood Prevention, Drainage Monitoring, Machine Learning, XGBoost, 3D Visualization, Pressure Analysis, Smart Infrastructure

I. INTRODUCTION

In recent years, urban flooding has emerged as a critical issue in urban areas, mainly because of urbanization and the occurrence of extreme rainfalls. Traditional systems of monitoring urban flooding have mainly been reactive, as the flooding is detected only when the accumulation of water is visible above the ground level. This is not effective in the detection of hidden conditions in the underground urban drainage systems, which occur over a long period and result in serious consequences such as the collapse of the road, displacement of manholes, and threats to the safety of people.

Hence, it is imperative to have an intelligent system of monitoring urban flooding, which is based on the early detection of abnormal conditions in urban drainage systems. Factors such as pressure, water level, and flow, which occur internally in the urban drainage systems, have a major impact in the detection of the conditions in the underground urban drainage systems. These conditions need to be constantly monitored and analyzed in order to detect problems such as blockages, presence of air, and increased pressure in the urban drainage systems.

In this regard, the suggested system has incorporated a smart monitoring feature, which entails the utilization of real-time monitoring and intelligent analysis of data to ascertain and predict possible risks in the drainage pipes. It examines the data gathered to establish various patterns, thereby classifying the condition of the pipes and determining the severity of blockage. Moreover, the system provides a 3D image of the underground drainage network, thereby facilitating easy identification of areas of high risk.

In addition, the suggested system has incorporated a preventive measure, which entails the release of excessive pressure from the pipes to avert possible damage. Therefore, the suggested framework is likely to improve the management of floods in urban areas.

II. LITERATURE SURVEY

Research studies have been conducted in the area of urban drainage monitoring and prevention of floods. The studies focused on enhancing the monitoring of floods in real-time.

In [1], a real-time early warning system for urban floods was presented. The study focused on the importance of monitoring floods in real-time through the collection of data from various sources. The research proved that monitoring floods in real-time helps in responding to floods in a much shorter time.

In [2], a monitoring framework for drainage systems was presented. The monitoring framework focused on monitoring the flow of wastewater in the underground drainage systems. The research focused on monitoring the water flow to prevent overflow in the systems. The monitoring framework, however, focused only on the surface-level monitoring of water flow.

In [3], a precise method of monitoring floods was presented. The research focused on directly monitoring the water flow in the environment. The research proved that directly monitoring the environment helps in responding to floods in a much shorter time compared to indirect methods of monitoring floods.

In reference [4], a scheme for the automated monitoring and control of the drainage system was introduced, in which parameters such as water level and flow rates can be monitored continuously. Although this was useful for decision-making, the focus was only on monitoring and not on predicting possible dangers or preventing failures.

In reference [5], a smart monitoring system for the drainage network was designed in order to improve urban sanitation and avoid risks of drainage inspection. This was useful, although the focus was only on monitoring and providing alerts to the authorities, and no advanced analysis was performed in order to predict possible dangers or failures.

In reference [6], a comprehensive review of the different monitoring techniques for urban floods was performed, emphasizing the importance of intelligent data-driven techniques. This was useful, although the importance of intelligent data-driven techniques was highlighted, and the importance of combining different data sources was mentioned.

In reference [7], a framework for the integrated modeling of the drainage network was introduced, which included data, prediction, and adaptive control. This was useful, although the importance of a dynamic response for a system was introduced, depending on the changes in the environment.

III. EXISTING SYSTEM

The conventional urban drainage monitoring system mainly focuses on the surface-level phenomena, such as the accumulation of water and the characteristics of the flow. In most cases, the system depends on the periodic inspection and basic sensing mechanisms to identify the overflow or blockage in the drainage system. The monitoring process mainly focuses on the identification of the problems after they occur, such as the stagnation of water or the flooding of the surface.

The parameters monitored in most cases are limited, such as the rate of the flow or the level of the water, and the conditions inside the system, such as the pressure and stress, are not taken into consideration. In most cases, the problems, such as the accumulation of air, blockage, and pressure, occur internally and cannot be identified. Moreover, the system does not offer automatic responses, and the intervention of humans is required to address the problems.

In addition, the systems in place currently do not have the ability to perform advanced analysis in the prediction of potential problems and the early signs of failure. There is a lack of visualization of the conditions in the underground drainage systems, and it is difficult for the authorities to understand the exact nature and location of the problems in the system. Therefore, the conventional systems currently in place in the management and monitoring of the urban drainage systems are not effective in the prevention of urban flooding

IV. DISADVANTAGES OF EXISTING SYSTEM

Lack of early detection, where the systems only detect problems once the flooding has already appeared on the surface
Lack of monitoring of internal pressure and stress in the pipes
Inability to detect hidden problems such as the presence of air pockets and blockages in the pipes
High dependency on manual inspection and maintenance, which is time-consuming
Lack of prediction and detection of potential problems in the system
Lack of clear visualization of the conditions in the underground pipelines
Lack of an active prevention mechanism to reduce internal pressure and prevent structural damage from occurring

V. PROPOSED SOLUTION

The proposed system aims to improve the management of urban floods through the monitoring of the internal conditions of the underground drainage pipelines, where the behavior of the systems will be identified early in case of any abnormalities. Unlike other systems, which are designed to detect floods after the accumulation of water on the surface, the proposed system aims to detect hidden subsurface conditions, which may cause failures or overflows.

In the proposed system, various sensing devices will be placed in strategic positions to detect critical parameters, including internal pressure variation, water level variation, flow, and internal disturbances. The devices will be used to gather data, which reflects the actual situation of the pipeline.

The data gathered from the pipeline will be processed to identify abnormal patterns, which may be associated with problems, including the formation of blockages, air pockets, and excessive pressures. The relationship between different parameters will be used to identify early signs of failures.

To enhance the quality of decision-making, the system has incorporated intelligent analysis of the data, which is learned from the real-time and historical data. This helps in the classification and prediction of potential problems in the pipelines. It also offers a visual representation of the underground drainage conditions, which enables the authorities to understand the potential problems.

Moreover, the system has incorporated a preventive component, which safely releases the excessive internal pressure through a controlled venting process. This is done based on the condition-based logic, where only the air is released and not the water. This is done through the design and monitoring-based control, which ensures the safety and efficient regulation of the pressure.

The system has also enabled the generation of alerts, which is a part of the maintenance aspect. This is done to ensure the efficient maintenance of the urban drainage systems. Therefore, the proposed system has incorporated the above-mentioned features, which enhance the quality and reliability of the urban drainage systems.

VI. ADVANTAGES OF EXISTING SYSTEM

Early Detection of Abnormal Conditions:
This system is able to detect abnormal conditions before flooding occurs. For example, it can detect possible problems with pressure buildup and blockages.

Continuous Monitoring of Drainage Network:
This system will provide a continuous observation of internal pipeline conditions rather than conducting periodical inspections.

Detection of Hidden Subsurface Problems:
This system will effectively detect subsurface problems, including trapped air pockets, internal pressure changes, and flow changes.

Improved Flood Prevention Capability:
This system will reduce the possibility of urban flooding.

Intelligent Decision-Making Support:
This system will support decision-making through data analysis for classifying and predicting possible failures.

Controlled Pressure Release Mechanism:
This system will release trapped air through a controlled process without causing water discharge.

Prevention of Infrastructure Damage:
This system will prevent damage to infrastructures, including road collapse, pipe damage, and manhole displacement.

Support for Preventive Maintenance:
It enables maintenance teams to undertake maintenance activities before a problem reaches a critical stage.

Clear Visualization of Underground Conditions:
It facilitates the easy identification of risk areas by the relevant authorities.

Reduction in Manual Inspection Effort:
It reduces the need to inspect the infrastructure manually, which is beneficial in terms of increased efficiency.

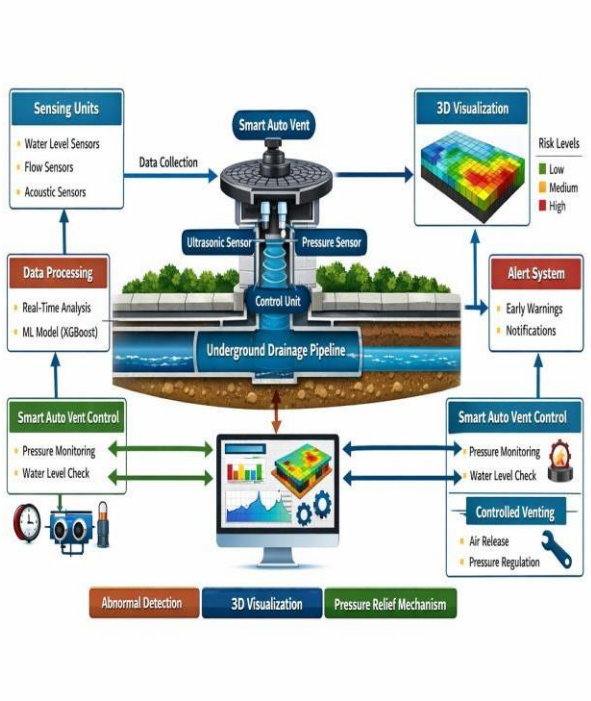
Faster Response to Critical Conditions:
It enables quicker responses to critical conditions.

Enhanced Public Safety and Environmental Protection:
It reduces risks to the public resulting from flooding, in addition to preventing health hazards resulting from stagnant water.

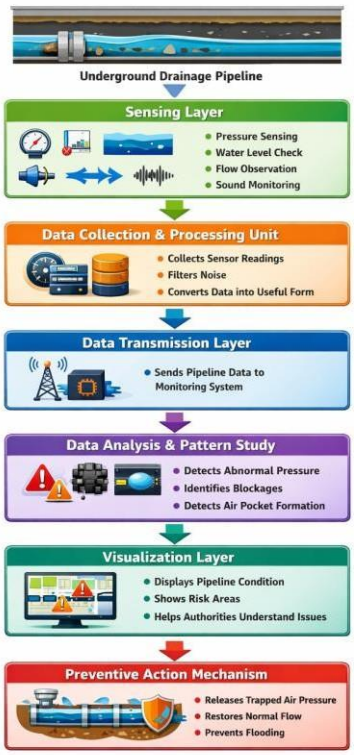
VII. COMPARISON WITH EXISTING SOLUTION

FEATURES	**CONVENTIONAL DRAINAGE MONITORING**	**SMART AIR POCKET DETECTION SYSTEM**
Operational Logic	Reactive: Response only after surface flooding is visible	Proactive : Predicts flooding by detecting subsurface Air compression
Primary Data Source	Surface water level and flow velocity	Multi model fusion : Air pressure, Water level and acoustic Signature
Analytic Core	Static Threshold (Binary high / Low alerts)	Machine learning (XG Boost) : Pattern Recognition and Anomaly classification
Detection window	0 lead time : Alerts occurs during the flood event	Early Warning : Provides 5-15 min of lead time via pneumatic analysis
Infrastructure Safety	Iris of manhole displacement and road cave - ins	Active mitigation : Smart auto vent releases trapped pressure anonymously
Network Resilience	Dependent on Wi - Fi / GSM (High Signal attenuation)	LoRa (Long Range): optimized for deep sub terranean Data transmission
System Visibility	2D, Graphical Dashboard (Line, Bar charts)	3D Digital twin : Real time spatial stress of pipe segments
Maintence Model	Corrective : Maintenance is performed for a failure	Predictive : “Health alerts” sent based AI detected clogs
Physical Intervention	Requires manual deployment to clean vents	Autonomous self cleaning sensors and motorized pressure relief

VIII. ARCHITECTURAL DIAGRAM



IX. WORKFLOW



X. CONCLUSION

The proposed system provides a reliable framework that ensures the improvement of the management of urban flooding through the constant monitoring of the underground drainage system. The system is able to monitor the internal parameters of the drainage system and thus detect any hidden problems in the subsurface drainage system. The incorporation of intelligent data analysis and the controlled release of pressure is able to prevent damage to the drainage system and thus flooding. The proposed system is able to improve the safety of the drainage system in the urban area

A Study On Impact Of Gamification On Employee's Motivation Towards Engagement

[1]Dr.Sofia Vincent , [2]R.Venassheni , [3]D.Ragavi , [4]S.Ramya, [5]R.Vidhya , [6]J.Tamil Selvi

[1]Assistant Professor, [2,3,4,5,6] MBA Students,

Panimalar Engineering College, Chennai-600 123

ABSTRACT

Gamification refers to the process of increasing the level of engagement of employees at the workplace through the implementation of game-related tools like points, rewards, and feedback. The aim of the study is to evaluate the influence of the gamified system on performance, as well as the understanding of the perceptions of employees across various organizations. A structured questionnaire was used as the data collection tool, and the findings were analyzed using percentage methods. The findings of the study show that the majority of the employees have a positive attitude towards the implementation of the gamification system, as they are motivated. However, others have no opinion, thus the need to enhance the implementation process. The study shows that gamification is a successful strategy in enhancing the engagement of employees, thus improving the performance of the organization.

Keywords: Gamification, Employee Engagement, Employee Motivation, Employee Perception, Organizational performance.

INTRODUCTION

In the current competitive business world, organizations are seeking ways to boost employees' motivation and engagement, which will result in improved performance. Employees' engagement is critical in boosting productivity, job satisfaction, and organizational success. However, boosting employees' motivation is a challenging task, especially considering the repetitive nature of their duties and the evolving nature of the work environment. Gamification is a new and innovative strategy for boosting employees' motivation. Gamification involves the application of game design elements, including points, badges, and leaderboards, and rewards in the work environment. These elements make employees' tasks engaging and interactive. Gamification is based on intrinsic and extrinsic motivational factors, which motivate employees to actively engage in their activities. Employees also feel connected and aligned with their organizations. This study explores the effects of gamification on employees' motivation and its contribution to boosting employees' engagement. In addition, this study will address the benefits and challenges associated with gamification in organizations.

REVIEW OF LITERATURE

Simeia Azevedo Santos et al. (2019) claim that gamification makes the training process more effective and increases employees' engagement, thus achieving a 20% to 200% improvement in performance via rewards and feedback. Ryan J. Baxter et al. (2014) assert that gamification makes the training process more enjoyable and satisfactory for employees; however, the effects of gamification on learning outcomes are unclear, and non-gamers benefit more than gamers. Alvear et al. (2021) point out that gamification increases employees' motivation, engagement, and understanding of complex activities in police force training, and employees develop better teamwork skills. Alfaqiri et al. (2022) argue that gamification increases employees' engagement in online training, and usability and value influence acceptance based on the Technology Acceptance Model (TAM). Hussain et al. (2018) emphasize that gamification increases employees' motivation, engagement, loyalty, and retention by making the workplace fun for employees. Kulkarni et al.

OBJECTIVES

- To understand the concept of gamification in organizations.
- To analyze the level of employee engagement in gamified workplaces.
- To examine the impact of gamification on employee motivation and performance.
- To study employee's perception towards gamified systems

METHODOLOGY

The main data collected for the study was collected with the help of a structured questionnaire. Likert scale, multiple-choice, and rating scale were used in the questionnaire to assess how employees felt about the communication and its impact on their motivation. The questionnaire was sent online using Google Forms, which provided greater outreach and convenience to the

respondents. A total of 196 questionnaires were sent out. Out of these, 152 were received. A total of 124 were complete and valid. So, the final figure considered for the research was 124..

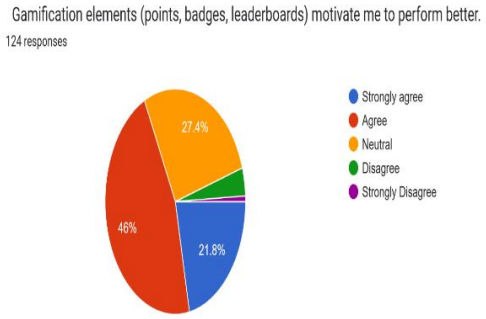
DATA ANALYSIS

Table showing impact of gamification on employee

S.No	Response Category	No. of Responses	Percentage (%)
1	Strongly Agree	27	21.80%
2	Agree	57	46.00%
3	Neutral	34	27.40%
4	Disagree	4	3.20%
5	Strongly Disagree	2	1.60%
	Total	**124**	**100%**

RESULT AND DISCUSSION

- 67.8% of the total who answered (Agree + Strongly Agree) said that gamification makes them want to improve more.
- A large number of individuals (27.4%) are still neutral, which implies that there is space for gamification to improve.
- Only 4.8% of the total said something bad, which implies that most were happy with it.



FINDINGS

The majority of the participants (67.8%) either agreed or strongly agreed with the statement that things like points, badges, and leaderboards in games make them want to do better. This shows that people have a very positive attitude towards gamification at work. The highest percentage of participants, i.e., 46%, chose the option of "Agree," which shows that the majority of employees are motivated, but the motivation might not be very strong. A good percentage of participants, i.e., 27.4%, chose the option of "Neutral," which shows that a lot of employees are either unaware of whether gamification actually works or are unaware of all the benefits of gamification. It has also been seen that only 4.8% of the participants said that they disagree, which shows that only a small percentage of employees are of the opinion that gamification does not work. The presence of the option of "Neutral" shows that the effectiveness of gamification might need to be enhanced. It has clearly been seen that the effectiveness of gamification towards motivating employees is good, and it can be used as a way of getting employees more involved.

LIMITATIONS

It is possible that the small number of samples in this study does not fully represent all employees. The results' generalization to other fields may be limited by the fact that the study was conducted in a certain area or institution. The results' authenticity could have been compromised by the fact that employees may respond in a way that is socially acceptable rather than their real feelings. The study was limited in time and could not assess the long-term effect. Responses that are neutral or false could result from some employees' lack of understanding of certain concepts in gamification..

CONCLUSION

Gamification is a strong and creative technique that modern-day organizations can use to increase their workforce's morale, productivity, and engagement. With effective strategies and further assessments, the effectiveness of gamification may be further heightened in the workplace. The study concludes that gamification has a significant impact on employee engagement and motivation in the workplace.

Most of the employees agreed that gamified systems are effective in improving their interest and participation in the workplace. This suggests that the incorporation of game elements in the workplace is effective in improving employee engagement and participation in the workplace. However, a significant number of the respondents were neutral, suggesting that gamification is effective.

"Viewer Attention and Distraction Behaviour While Watching Movies: A Comparative Study Of OTT And Theatre Audience."

[1] Dr .K. Suresh kumar, [2]Ragamaliga.J , [3]Pooja.K , [4]Raksha.R , [5]Rithika.S, [6]Sneha.K,

[1] Professor . [2,3,4,5,6] MBA Student

ABSTRACT

The rapid growth of Over the Top (OTT) content service providers such as Netflix and Amazon Prime Videos has changed the way people are consuming movies, shifting from the traditional theatre experience to more personal digital viewing spaces. The audience's focus and distraction propensities in OTT and theatre viewing spaces have been researched and compared in this study. OTT offers the benefit of flexibility, which in turn has increased distraction propensities, while theatre viewing offers a more immersive experience, thus aiding concentration. The main aim of this study is to examine the psychological effects of both mediums of viewing, the factors that influence attention span, and the behavioural differences. The findings of this study are intended to contribute more information to the field of media studies, which would help the developers and makers of OTT and other digital viewing platforms understand the viewing behaviours and trends of the audience.

INTRODUCTION

With this shift from conventional theatre experience to more tailored digital mediums, the proliferation of Over-The-Top (OTT) services such as Netflix and Amazon Prime has revolutionized how consumers consume their movie content. This study explores and compares how consumers in OTT and theatre environments maintain attention and get distracted while watching content. Theatre offers a controlled experience, which is beneficial for sustained attention, while OTT services, with their flexibility, create more distractions for consumers. This study will assess the psychological effects of both consumption methods, determine factors influencing attention span, and highlight how there are significant behavioural differences in consumers' engagement with content, which will further aid in advancing media studies as a discipline.

Need of study

Movie viewing has moved from the theatre to home-based streaming through the explosive growth of OTT platforms. Key issues concerning differences in viewer attention and distracting behaviours are raised. While home-based streaming services provide ease of access and cause distraction through multitasking and mobile use, theatre-based streaming is a controlled and engaging environment that enhances viewer attention. It is vital to understand these differences because viewer attention and information processing are directly affected. However, few research studies are available that compare the levels of attention between the two platforms. To provide insights to enhance viewer experiences and content delivery approaches, this study compares and analyzes viewer attention and distraction behaviours in theatre-based and home-based streaming.

Objectives

- To study how viewer attention and distraction behaviour is influenced by demographic factors such as gender and age while watching movies in theatres and OTT platforms.
- To study how viewer attention and distraction behaviour is influenced by platform preference, such as watching in theatres versus OTT platforms, and how frequency affects viewer attention and distraction behaviour.
- To study how the level of viewer attention while watching movies in theatres and over-the-top (OTT) platforms compares with each other.
- To study how viewer attention and distraction behaviour are influenced by mobile phone usage while watching movies in over-the-top (OTT) platforms as opposed to watching in theatre.
- To study how viewer attention will be influenced by factors such as multitasking and distractions while watching movies in theatres and over-the-top (OTT) platforms.

• To study how viewer attention will be influenced by factors such as how often people engage in activities such as eating, texting, and browsing while watching a movie in theatres as opposed to watching in OTT platforms

Scope

This study is about how people pay attention and get distracted while watching movies in theatre and while streaming them. It also checks different age groups and how they watch movies to check how their habits change. It includes how people use their phones, watch multiple things at once, and how people get distracted by external sources while watching movies, which helps in finding out how much they enjoy the movie. It helps in understanding which way of watching movies keeps them more interested and how people get distracted in theatre and while streaming. This helps in making watching movies more interesting for everyone by understanding how people behave while watching movies.

Limitations

The study is just based on a few people, so it may not be applicable to all people. The study is based on general watching habits, so it does not go into detail about different types of shows or how people feel inside. The place they are, how they feel, and who they are with can all play a part in how they pay attention, but this is not fully discussed in this study.

Review of Literature:

Lalit Kumar (2023) The study looks at how Over-The-Top (OTT) platforms affect the movie business, with an emphasis on how viewers' habits are shifting in favour of greater affordability and convenience. The study, which used a mixed-methods approach with 300 moviegoers surveyed and 10 expert interviews, comes to the conclusion that although OTT platforms have increased the reach of films, they have also decreased traditional cinema attendance among younger demographics.

Dr. Rajeshwari (2025) This study is about how people in India watch movies and it is changing. The study compares what people like to watch. How they can watch it with the old way of going to the cinema. It looks at things like how much it costs if people can get to it and what age groups like what by reading reports from the industry and things that academics have written. The study found out that online platforms like Netflix are now a part of the media industry more than 30%. This is because younger people like it when things are easy for them. Because of this less and less people are going to the cinema, which means that traditional cinemas need to think of ideas really fast. The cinemas need to do something because online platforms, like OTT platforms are getting more popular and people like watching movies on OTT platforms.

Dr. pavala kumar (2022) This study examines how the "Anyone, Anywhere" phenomenon has led to a transition from traditional cinema to over-the-top (OTT) platforms. The study, which was carried out using 300 questionnaires, 10 expert interviews, and secondary data, demonstrates a substantial shift toward digital streaming even if theatres provide a cultural, superior sensory experience. Results indicate that OTT now holds more than 30% of the market, driven by younger audiences' preference for price and convenience (18–35). In the end, the study comes to the conclusion that in order to compete with the quick expansion of digital platforms, traditional theatres need to innovate.

RESEARCH METHODOLOGY

Research methods define a systematic process of finding, assessing, analysing, and drawing conclusions about a particular area of research. These methods will include the techniques, methods, and tools researchers use to perform their research, ensuring reliable, accurate, and valid results.

DESCRIPTIVE RESEARCH

Researchers use descriptive research design as an effective means of collecting data about a group of individuals/subjects. The results of this type of research will look at a population or sample and accurately reflect the characteristics and patterns of behaviours exhibited by that population/sample. Researchers can collect the qualitative data needed to understand a specific topic by observing and collecting data, and possibly producing data to guide any additional studies.

SIMPLE RANDOM SAMPLING

When conducting basic random sampling, a researcher randomly selects a sample of individuals from a larger sample/population that is representative of all people who belong to the target population. With simple random sampling, the individual selections are equally likely to be selected, as determined by the probability of their being included in the random sample. Many researchers and statisticians rely on sampling techniques such as this to obtain representative samples from their target population.

SAMPLE SIZE

This study was conducted on the entire population for the proposed study includes all individuals regardless of gender. The sample was collected equally and shows the sample size is 85.

The data for the sample sizes provides in this study were obtained from surveys.

TEST OF NORMALITY

Null Hypothesis (Ho): The data follows normal distribution.

Alternative Hypothesis (H1): The data does not follows normal distribution.

Tests of Normality

	Kolmogorov-Smirnov[a]			Shapiro-Wilk		
	Statistic	df	Sig.	Statistic	df	Sig.
To examine the effects of platform preference (OTT vs. theater) and viewing frequency on the attention and distraction behaviors of moviegoers.	.228	81	<.001	.920	81	<.001
To compare the degree of viewer focus when watching films on over-the-top (OTT) platforms and in theaters.	.153	81	<.001	.946	81	.002
To investigate how mobile phone use affects viewers' attention and distraction patterns when watching movies on over-the-top (OTT) platforms as opposed to theaters.	.195	81	<.001	.921	81	<.001
To examine how multitasking and outside distractions affect viewers' attention when they watch movies in theaters and on OTT platforms	.150	81	<.001	.950	81	.003
To ascertain which platform results in a greater frequency of multitasking (such as eating, texting, or browsing) while watching a movie	.316	81	<.001	.823	81	<.001

a. Lilliefors Significance Correction

Inference

From the table, the significance value (p-value) is less than 0.05. This indicates that the null hypothesis (H_0) is rejected. Hence, the data does not follow a normal distribution.
Since the data is not normally distributed, a non-parametric test is considered more suitable for further analysis.

NON PARAMETRIC-TEST

Non-parametric tests are tests that do not require strong assumptions about the population. They are tests that do not require data to follow any certain probability distribution. This makes them more realistic for real-world data, as real-world data does not always follow normal distributions.

TOOL USED IN THIS STUDY

- Compare means (independent t-test)

TEST ANALYSIS

NON-PARAMETRIC TEST

- **Compare Means**

Null Hypothesis(Ho): There is no significant difference between age and distractions.
Alternative Hypothesis(H1): There is significant difference between age and distractions.

Group Statistics

	What is your age group?	N	Mean	Std. Deviation	Std. Error Mean
When watching movies in theatre, how attentive are you to the movie?	18-20	16	1.81	.834	.209
	21-30	65	1.88	.839	.104
When watching movies on ott, how attentive are you to the movie?	18-20	16	2.00	.816	.204
	21-30	65	2.17	.741	.092
Overall, where do you experience more distractions while watching movies?	18-20	16	1.44	.629	.157
	21-30	65	1.62	.722	.090

INFERENCE

The results reveal that the attention level of both age groups, i.e., 18-20 and 21-30 years, is similar while watching movies. However, the 21-30 age group is slightly more attentive than the 18-20 age group while watching movies in both theatres and OTT. The 21-30 age group faces a little more distractions than the 18-20 age group.

Independent Samples Test

		Levene's Test for Equality of Variances		t-test for Equality of Means						
						Significance				95% Confidence Interval of the Difference
		F	Sig.	t	df	One-Sided p	Two-Sided p	Mean Difference	Std. Error Difference	Lower	Upper
When watching movies in theatre, how attentive are you to the movie?	Equal variances assumed	.075	.784	-.276	79	.392	.784	-.064	.234	-.530	.401
	Equal variances not assumed			-.276	23.059	.392	.785	-.064	.233	-.546	.418
When watching movies on ott, how attentive are you to the movie?	Equal variances assumed	.157	.693	-.802	79	.212	.425	-.169	.211	-.589	.251
	Equal variances not assumed			-.756	21.491	.229	.458	-.169	.224	-.634	.296
Overall, where do you experience more distractions while watching movies?	Equal variances assumed	1.254	.266	-.903	79	.185	.369	-.178	.197	-.570	.214
	Equal variances not assumed			-.983	25.677	.167	.335	-.178	.181	-.550	.194

INFERENCE

The results show that there is no significant difference between the two age groups in their attention levels or distractions while watching movies in theatres or on OTT platforms. Age does not appear to influence viewing behaviour in a meaningful way. Hence , the p value is more than 0.05 we reject HO

Null Hypothesis(Ho): There is no significant difference between gender and distractions.

Alternative Hypothesis(H1): There is significant difference between gender and distractions.

Group Statistics

	What is your Gender?	N	Mean	Std. Deviation	Std. Error Mean
When watching movies on ott, how attentive are you to the movie?	male	57	2.18	.735	.097
	female	24	2.04	.806	.165
When watching movies in theatre, how attentive are you to the movie?	male	57	1.81	.833	.110
	female	24	2.00	.834	.170
Overall, where do you experience more distractions while watching movies?	male	57	1.58	.706	.093
	female	24	1.58	.717	.146

INFERENCE

The results show slight differences between males and females in attention levels. Males are a bit more attentive while watching movies on OTT platforms, whereas females show slightly higher attention in theatres. However, when it comes to distractions, both males and females report the same level. Overall, the differences are minimal, indicating that gender does not strongly influence attention or distraction while watching movies

Independent Samples Test

		Levene's Test for Equality of Variances		t-test for Equality of Means							
						Significance				95% Confidence Interval of the Difference	
		F	Sig.	t	df	One-Sided p	Two-Sided p	Mean Difference	Std. Error Difference	Lower	Upper
When watching movies on ott, how attentive are you to the movie?	Equal variances assumed	.453	.503	.727	79	.235	.470	.134	.184	-.233	.500
	Equal variances not assumed			.699	39.894	.244	.488	.134	.191	-.253	.520
When watching movies in theatre, how attentive are you to the movie?	Equal variances assumed	.012	.911	-.952	79	.172	.344	-.193	.203	-.597	.211
	Equal variances not assumed			-.951	43.253	.173	.347	-.193	.203	-.602	.216
Overall, where do you experience more distractions while watching movies?	Equal variances assumed	.001	.977	-.025	79	.490	.980	-.004	.173	-.348	.339
	Equal variances not assumed			-.025	42.662	.490	.980	-.004	.174	-.355	.346

INFERENCE

The results show that all p-values are greater than 0.05, indicating no significant difference between males and females in attention levels while watching movies on OTT or in theatres, as well as in experiencing distractions. In simple terms, gender does not have a meaningful impact on viewing behaviour.

Hence, the p value is more than 0.05 we reject H0

FINDINGS

- The analysis shows that age and gender do not significantly influence viewer attention or distraction behaviour while watching movies in theatres or on OTT platforms.
- There is no major difference in attention levels between viewers who prefer OTT platforms and those who prefer theatres, indicating similar engagement across platforms.
- Viewers tend to show slightly better focus in theatres compared to OTT platforms, but the difference is not statistically strong.
- Mobile phone usage is higher during OTT viewing, which slightly increases distraction levels compared to theatre watching.
- Multitasking and external distractions (like using phones, talking, or browsing) are more common on OTT platforms than in theatres.
- OTT platforms result in a higher frequency of multitasking activities such as texting, eating, or browsing, whereas theatres provide a more controlled and less distracting environment.

SUGGESTIONS

- There is no major difference based on age or gender, so awareness about focused viewing can be promoted equally for all groups. Encouraging mindful watching habits can help improve attention for everyone.
- Since platform preference has little impact, viewers should focus more on how they watch rather than where they watch. Maintaining regular and distraction-free viewing habits can improve attention levels.
- Viewers can choose theatres when they want a more immersive and focused experience. While using OTT, creating a theatre-like environment at home can help improve concentration.
- Reducing mobile phone usage while watching movies can significantly improve attention. Viewers should try to avoid checking phones frequently, especially during OTT viewing.
- Avoiding multitasking like chatting or browsing can help maintain better focus. Creating a quiet and distraction-free environment can enhance the viewing experience
- Since multitasking is higher on OTT platforms, viewers should consciously limit such activities. Practicing single-task viewing can help increase engagement and enjoyment.

CONCLUSION

The research concludes that although the emergence of OTT platforms has led to a further personalization of the space for watching movies, there is no statistically significant difference between the attention and distraction levels of males and females. Although OTT provides the advantage of personalization, it is often linked to the presence of distractions and multitasking, unlike the immersive environment of the theatre. It was observed that, although the attention levels were higher for the 18-20 and 21-30 age groups on the OTT platform, the subjects also experienced a higher level of distractions. According to the research, it was observed that since the gender of the viewer does not play a major role in the overall viewer behaviour, it is recommended that both the OTT platform and the theatre owners must look for technical innovations to keep the viewers engaged.

A Study On The Impact Of Discounts And Promotional Offers On Impulse Buying Behavior

[1]S. Sakthikumar , [2]J. Tamilselvi , [3]G. Mithra , [4]L. Sandhiya , [5]S. Swathi

[1]Skilled Assistant [2,3,4,5]MBA Students, Panimalar Engineering College, Chennai-600123

ABSTRACT:

In today's competitive retail environment, discounts and promotional offers have become powerful tools to attract consumers and increase sales. This study examines how such marketing strategies influence impulse buying behaviour among consumers. Using a questionnaire-based approach, the research focuses on individuals aged 15–30 to understand their purchasing patterns and reactions to various promotional techniques. The study highlights both positive aspects, such as increased customer satisfaction and perceived savings, and negative aspects, including unplanned spending and financial strain. The findings provide valuable insights for marketers, retailers, and consumers to understand the psychological triggers behind impulse buying. Ultimately, the study emphasizes the need for responsible marketing strategies and conscious consumer decision-making.

Keywords: Impulse Buying Behaviour, Discounts, Promotional Offers, Consumer Psychology, Sales Promotion, Unplanned Purchases, Marketing Strategies.

INTRODUCTION

However, the retail market has changed dramatically over time because of the use of discounts and other promotional offers as marketing tools. The use of such tools is prevalent among businesses to attract customers and increase their sales and brand awareness. The increasing popularity of online shopping and other digital platforms have made customers aware of different types of promotional offers every day. Hence, the phenomenon of impulse buying is more prevalent than ever.

Impulse buying is defined as the spontaneous and unplanned buying behavior of customers without any pre-planned intentions. The use of discounts and other promotional offers is very important to influence the perception of customers..

Psychological factors like the value of the product, fear of missing out, and emotional satisfaction are the major factors that contribute to impulsive buying behavior. Promotional offers may provide the illusion of saving money even though the product is not required at the time of purchase. Although promotional offers may increase customer satisfaction and provide benefits, they may also contribute to overspending and lack of control among the consumers.

In the city of Chennai, the impact of promotional strategies is higher due to the availability of online shopping platforms, the increase in income levels, and the exposure to digital marketing campaigns. Consumers, especially young people, may be influenced by promotional offers and advertisements..

The objective of this study is to analyze how discounts and promotional offers can affect impulse buying behavior in consumers. This study will be able to provide insights to marketers, retailers, and policymakers by understanding consumers' purchasing habits, psychological factors, and responses.

Understanding how consumers are influenced by promotional offers can be beneficial in creating effective promotional strategies while promoting good consumer behavior.

REVIEW OF LITERATURE

There are many studies showing the impact of discounts and promotions on the way people buy things on impulse. It has been seen that when people see discounts, coupons, and other offers, they buy more things on impulse. It has also been seen that when people think they are getting good discounts, they buy more.

In the study done by Lestari and Dalimunthe, it has been seen that discounts and promotions have a positive impact on the way people buy things on impulse, especially when they are shopping online. Anggarwati and others have also seen the same thing, as they have noted that when there are promotions like flash sales or cashback, people feel like they have to buy the things away or they will miss out.

For instance, Oberoi did some research that shows how discounts can make people feel happy and excited and this makes them want to buy things without thinking about it. People don't only save money through discounts; they also feel good. Therefore, this makes them buy things on impulse.

Some research also shows that if the discounts are only available for a certain period of time, it can make people feel that they have to buy things as soon as possible. This is

because they don't want to lose the discounts. The youth who use the internet to shop a lot feel this way.

However, some researchers feel that too many promotions can be bad for people. The researchers found that when people buy things on impulse as much as they can, they can spend too much money and not be in control of their finances. People can also get used to relying too much on discounts and promotions.

Overall, the research demonstrates that discount and promotion are ways to influence people to purchase and engage in certain activities with companies, but at the same time, it also influences people's behavior and thinking. It is therefore necessary to understand this influence in order for companies to plan marketing strategies and help people make good decisions in their shopping activities.

OBJECTIVES OF THE STUDY

The study examines how people are influenced by discounts and promotional offers in making impromptu purchases.It tests how people are influenced by promotional offers in making impromptu purchases.The study examines how people are influenced by emotions such as excitement and fear of missing out in making impromptu purchases.The study finds out the bad impacts of promotional offers, how people are influenced to behave when making purchases.It tests how people are influenced by promotional offers in making impromptu purchases.The study evaluates how people are influenced by price discounts in making impromptu purchases.

RESEARCH METHODOLOGY

This research is looking into how discounts and special offers influence how people buy things on impulse. We used a research plan to achieve this. We had many people out there to research on; we decided to research on just a number of them. We got information through asking people to tell their friends about this research. We got information from two places. We asked people questions through a questionnaire. We also got information from other people who have written about this research in articles and on the internet. We looked at the information we got to see if we can identify any patterns. The main idea of this research is to understand how special offers and discounts make people feel.

DATA ANALYSIS AND INTERPRETATION

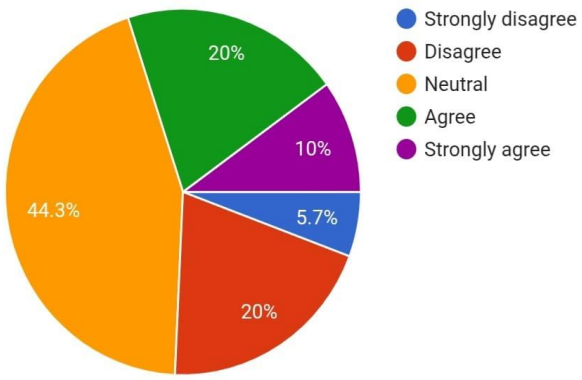
TABLE SHOWING THE INFLUENCE OF DISCOUNTS AND OFFERS ON IMPULSE BUYING

S.NO	PARTICULAR	NOMBER OF RESPONDENTS	PERCENTAGE
1	STRONGLY DISAGREE	2	2.9%
2	DISAGREE	12	17.1%
3	NEUTRAL	34	48.6%
4	AGREE	16	22.9%
5	STRONGLY AGREE	6	8.6%
	TOTAL	70	100%

INTERPRETATION

It was found that the majority of the respondents, i.e., 48.6%, were found to be neutral about the impact of discounts and offers on impulse buying behavior, and only a small percentage, i.e., 2.9%, were found to disagree. In all, the majority of the respondents were found to neither support nor oppose the impact of promotional offers on their buying behavior.

CHART SHOWING DISCOUNTS AND OFFERS MAKE ME SPEND MOREMONEYOVERALL



FINDINGS

Majority of respondents (65.7%) fall in the age group of 21-25 years. Out of the total respondents, 60% are female and 40% are male. It is found that the majority of respondents (68.6%) are students, followed by (25.7%) working professionals and (5.7%) self-employed. It is found that the majority of respondents (42.9%) shop sometimes during discounts and sales. Out of the total respondents, 32.9% prefer to use Flipkart, 24.3% use Myntra, and 20% use Amazon. Out of the total respondents, 35.7% prefer to purchase clothing and fashion products during offers, followed by 21.4% electronics products, 20% groceries, 15.7% beauty and personal care products, and 7.1% accessories.

The majority of the respondents spend between ₹3000 - ₹5000 (34.3%) or less than ₹1000 (32.9%) while shopping. Approximately 25.7% of the participants agree that limited time offers affect them to make quick decisions while shopping. The responses are inclined towards agreement (25.7%), which implies that the offers and discounts make the consumers excited. The majority of the participants (21.4%) agree that they buy the products on discount even if they are not needed. The responses are inclined towards agree and neutral (42.9%), which implies that the discounts moderately affect the consumers. The responses are mainly inclined towards neutral (42.9%), which implies that the participants neither agree nor disagree with the statement of buying more than needed while shopping on discount. The responses are inclined towards agree (40%), which implies that the discounts make the consumers try new brands and products. The responses are mainly inclined towards agree (40%), which implies that the consumers feel happy while shopping on discounts. The responses are inclined towards neutral (42.9%), which implies that the consumers may feel regret while shopping on discounts..

On the whole, the responses show a lean towards the neutral category (48.6%), which implies that discounts and promotional offers have a moderate influence on the impulse buying behavior of consumers**.**

CONCLUSION

From the research study, it is evident that discounts and promotional offers have a moderate influence on the impulse buying behavior of consumers. The research study revealed that the majority of the respondents show interest in products that are offered at discounts and promotional prices. The research study also revealed that consumers get motivated to buy products that they had no plans to buy. The research study revealed that consumers feel excited and happy to see discounts and promotional offers. The research study revealed that consumers show willingness to try new brands and products. The research study revealed that discounts and promotional offers have a moderate influence on the impulse buying behavior of consumers**.**

Attitudes Of Employees Towards Gender Equality In Educational Instituitions

Jenitha G[1], Hemasri D[2], Anandhi A[3], Keerthi Vaheni S[4], Pavithra N[5], Christy Jasmine R[6]

[1,2,3,4,5,6]Students I MBA , Department Of Management Studies

Panimalar Engineering College ,Chennai, India

ABSTRACT

The purpose of the study is to evaluate the attitude of the employees regarding gender equality in educational institutions. The research design of the study is based on 74 samples with the help of a structured questionnaire. The statistical tools are Pearson correlation and the Mann-Whitney U test, which are used in the research paper to evaluate the differences in the opinions of the employees regarding gender equality in educational institutions. The research paper revealed that the employees are in favor of gender equality in various aspects, such as payment, responsibility, and opportunities, but differ in terms of gender and individual differences in the attitudes of the employees regarding gender equality in educational institutions. The research paper revealed that the working environment is one of the most important factors in the promotion of gender equality in educational institutions.

INTRODUCTION

At the present time, gender equality has become a significant issue, as more and more educational institutions are committed to ensuring an equal opportunity for both genders within their respective systems and will have a profound impact on how students learn and develop. Although educational institutions are generally focused on providing students with factual information, schools and universities also have a responsibility to instill values and beliefs in their student bodies, and how employees view, perceive and feel toward gender equality could potentially positively or negatively impact their ability to reach their objective concerning equality.While educational institutions have made substantial advances toward achieving equality, there are still a number of areas and situations in which discrimination and/or bias are ubiquitous, such as when it comes to making hiring decisions; awarding promotions; making decisions and/or providing advice and guidance; or, interacting with students on a daily basis. Also, an employee's thoughts and actions regarding the gender equality process can also have a direct impact on an educational institution as well as the entire community in which a school is located.The attitudes of employees create a healthy and positive work environment that is welcoming, respectful, and supportive for all employees. In contrast, if employees have a negative attitude toward gender equality, they will reinforce negative stereotypes and limit opportunities for certain groups. Therefore, an employee's view on gender equality is extremely important.This study aims to explore how college and university employees view gender equality, and also to find out what factors might influence these views.

GENDER EQUALITY

Employees working in educational institutions have different opinions about gender equality. Some employees have strong opinions that both men and women should be treated equally in all aspects of the work. They have a positive attitude towards gender equality. They support the idea of equal pay and responsibility. Such attitudes

of employees help build a friendly environment.On the other hand, employees may have biased opinions about gender equality. Their opinions may have been influenced by their culture and society. They may think that women or men can handle certain tasks. Such attitudes of employees may lead to inequality among employees. The growth of other employees may also be affected.Employees can be made aware of the importance of gender equality through workshops or seminars. Such programs can help build positive attitudes among employees. By educating employees about gender equality, inequality can be avoided.Managers of the organization can play a vital role in building positive attitudes among employees. The manager must have good attitudes towards employees. He must treat both men and women equally. By observing the attitude of the manager, employees may also try to build good attitudes towards other employees.

OBJECTIVES

To analyze if male and female employees are treated equally in terms of salary, job responsibilities, and involvement in institutional decisions.

- To compare the attitude of different groups of employees towards gender equality on the basis of age, gender, and job.
- To identify the effective ways to overcome gender inequality in educational institutions.

- To analyze the ways the institution supports gender equality by providing equal opportunities and implementing gender equality policies for sustainable development.

REVIEW OF LITERATURE

Armando Calabrese., et al (11 july 2018) Previous studies suggest that certain personality characteristics may influence the way stakeholders view corporate social responsibility (CSR). In this study, employee attitudes toward CSR demandingness, trust, and satisfaction are examined, focusing on whether these differ by gender, age, and education level. The study is based on a survey of 153 employees of 11 Italian banks, along with an analysis of the sustainability reports of these banks. The reason for choosing the Italian banking industry is the recent spate of scandals involving finance and CSR-related issues. The study shows that, overall, men tend to trust and be satisfied with the efforts of their company in the area of CSR slightly more than women. Graduates tend to be much more demanding, much more trusting, and generally more satisfied with their company's efforts in the area of CSR than non-graduates. The difference between the perceptions of the older and the younger workforce is not significant. This method may help in the creation of effective CSR strategies by shedding light on the perceptions of the workforce regarding the company's efforts in the area of CSR.

sidlauskienė.,et al (2013) The field of study for this research was the STEM faculties in a University in Lithuania, and the respondents were all faculty members, researchers, and representatives of the institution. The main objective was to examine the role of institutional culture in the implementation of the initiative of the European Union, which seeks to effect structural changes in research institutions towards gender equality, especially for women in STEM disciplines. This is achieved through various tools such as the development of a conceptual framework, methodological guidelines for structured institutional transformation, and the application of an approach that uses the construction of models for multi-level institutional change. The findings revealed that, although there is an increased participation of women in higher education, there are reduced research opportunities for them as a result of backlash in institutional culture. This indicates a disconnect between gender equality theory and practice, thus calling for transformational change

- **L. Tavdgiridze.,et al (2021)** The aim of this research is to examine teachers' understanding of gender equality in Georgia's education system with a view to expanding the opportunities for schoolgirls in public life and with respect to the gendered knowledge constructed by means of schooling. The study was conducted with a sample of about 80 teachers, selected from the schools in the city of Batumi who taught technical, humanitarian, biological and civic subjects at various levels (primary, secondary and higher). Conducted in 2019–2020, the study employed focus group, telephone interview, and internet survey methods. The students' attitudes toward gender were largely shaped by their teachers, who said they often see traditional gender roles as natural and gender inequality as marginal. The conclusion of this study is that teachers need to be aware, updated with information and given teaching materials so that they would develop supportive attitudes on Gender Equality.

Tindara Addabbo, et al (2018) This paper proposes a fuzzy expert system specifically designed for gender equality assessment in higher education. The assessment was conducted in six universities in Europe, namely Italy, Lithuania, Finland, Germany, Portugal, and Ukraine, as part of the EQUAL-IST Horizon 2020 program. The program aims to implement gender equality plans in universities that are active in ICT research. This paper proposes a cognitive model using a Fuzzy Expert System (FES) that simulates the way experts think and learn, providing a compact measure of gender equality in an institution. The proposed index has a range of 0 to 1, with higher numbers indicating greater equality. The rules used in the fuzzy expert system are derived from expert opinions and the participatory concept of gender equality, as used in the EQUAL-IST project. The results of the gender equality index are expected to differ mainly on a national level, identifying key areas where new policies are required for gender equality. In addition, the proposed gender equality index will be compared with the perceptions of the participants regarding gender equality in the project.

Anna Zagrebina, (aug 25 2020) The purpose of the study is to understand the role of democracy in shaping gender beliefs through an examination of society itself. It also attempts to fill an important gap in the existing body of research, which has not adequately addressed the role of the differing democratic environments in shaping gender beliefs. The study adopted the comparative approach in understanding gender attitudes, using data from 72 countries to measure opinions in four domains: politics, business, higher education, and employment, and the role of democratization in shaping public opinions. By adopting this approach, the study covers the entire spectrum of less democratic societies and more democratic societies, providing a global perspective on the role of society in shaping the opinions of the people in the country. The study found that higher levels of democratization are associated with egalitarian gender attitudes, but the underlying sources of these gender attitudes differ significantly depending on gender and the socio-political setting of the country.

RESEARCH METHODOLOGY

1.RESEARCH APPROACH

We wanted to learn how employees at education institutions perceive gender equity. We did this by both describing and analyzing the opinions they have.

2.SAMPLE AND POPULATION

Our research focused on getting responses from all

employees at the institution, including all staff members as well as teachers, we had a sample of 74 individuals who completed the survey. In addition, they were able to respond to the survey because of their availability and willingness to participate.

DATA COLLECTION PROCEDURE

The primary tool we employed to gather data was a comprehensive questionnaire; additional sources of information included additional reference material in the form of articles, journals, and reports.

RESEARCH INSTRUMENT

The questionnaire consisted of a Likert scale, where participants were able to indicate how much they agreed or disagreed (on a range from a "strongly agree" to a "strongly disagree") with a particular item in the context of gender equity. In addition, a number of demographic question items were employed (e.g. gender, age, job-related experience), which were used to develop a profile for respondents; in contrast, question items relating to attitudes toward gender equity were constructed as the second part of the questionnaire.

VARIABLE INFORMATION

The independent variables in the study are gender, age, job role, and experience. The dependent variable we measured in the study was the respondents' attitude toward gender equity.

Tools and Techniques

We used the following tools and techniques when collecting data
We used Pearson Correlation to examine whether factors like experience were related to perceptions of gender equality.
We used Mann-Whitney U Test to compare people's perceptions of gender equality across one or two groups; for example, men versus women.

Data Analysis

Gender Distribution by Percentage Total Respondents = 74
Male = 23; Female = 51;
Percentages: Male = (23/74) * 100 = 31.1%; Female = (51/74) * 100 = 68.9%

At the group level, females accounted for 68.9% of all survey respondents; thus, the sample is predominantly female.

Mann-Whitney Test

Rankings by Gender
Male Mean Ranking = 35.70;
Female Mean Ranking = 38.31;
Mann-Whitney U Test Statistics:
Mann-Whitney U=545.00; Z Value = -0.496;
2-tailed P-value (Sig.) = 0.620;

P-value (Sig.) > 0.05, therefore, the result is not statistically significant.

FINDINGS

The research reveals that there are no significant differences between the two genders in the attitudes towards gender equality. Institutional support and efforts to address inequality have a weak relationship, which implies that: There may be policies, but the support for them is limited.
The research reveals that there are no significant differences between the two genders in the attitudes towards gender equality. Institutional support and efforts to address inequality have a weak relationship, which implies that: There may be policies, but the support for them is limited.

INTERPRETATIONS

Relationship between institutional support for gender equality and the equal treatment of employees This implies that the correlation value is 0.486. This clearly indicates that there is a moderate positive relationship. The implication of this is that if there is more institutional support for gender equality, it is
highly likely that the employees feel that both men and women are treated equally in terms of salary and other aspects. The significance value is < 0.001. This clearly indicates that the relationship is statistically significant. This clearly indicates that the relationship is not due to mere coincidence.
Relationship between institutional support and measures to reduce gender inequality
This implies that the correlation value is 0.084. This clearly indicates that the relationship is very weak. The implication of this is that institutional support does not have a relationship with identifying measures to reduce gender inequality.
The significance value is 0.473. This clearly indicates that the relationship is not significant. This clearly indicates that the relationship is not strong enough to make a conclusion.

SUGGESTION

The study shows that educational institutions help promote gender equality by providing equal opportunities and following proper policies. The results indicate a moderate positive relationship ($r = 0.486$, $p < 0.001$), meaning better institutional support leads to better perception of equality among employees. The Mann–Whitney U test also shows no

significant difference between male and female employees' attitudes. This means both groups share similar views on gender equality. Therefore, institutions should continue improving policies, create awareness, and maintain a fair and inclusive work environment for all employees.

CONCLUSION

The aim of this study was to investigate the attitudes of the employees concerning gender equality and how institutional support can contribute to this.From the results of this study, it is clear that there is no significant difference in attitudes concerning gender equality between male and female employees. Both have the same attitudes and perspectives concerning this issue. Therefore, it is clear that gender is of no influence on how employees perceive gender equality in the workplace.Moreover, this study revealed that there is no strong link between institutional support and how well this contributes to the reduction of gender inequality. This may imply that such attempts may not be sufficiently effective.This study also points out that although employees have positive attitudes concerning gender equality, this is different from how well gender equality policies are implemented and recognized.gender inequality to be reduced in the workplace, more emphasis needs to be put on how well gender equality policies are implemented and recognized in order for them to contribute positively to the reduction of this social problem.

A Study On The Impact Of Business Analytics On Improving Hiring Efficiency In IT Companies From A Candidate Perspective

[1]Radhiga.R, [2]Archana.R, [3]Jaya Shree.B, [4]Bhavya.G

[1234]Department of Management Studies, Panimalar Engineering College, Chennai, India

Abstract:

This study examines the impact of business analytics on improving hiring efficiency in IT companies from a candidate perspective. The study focuses on key factors influencing hiring efficiency such as communication, time taken in recruitment, use of analytics-based evaluation methods, and challenges faced during the hiring process. To understand the role of analytics in enhancing recruitment outcomes and candidate experience. To identify the areas where improvements can be made in the hiring process and to suggest suitable recommendations. Through a structured questionnaire, the perceptions of respondents who have experienced recruitment processes are analyzed. A sample size of 137 respondents was collected using non-probability sampling techniques. The statistical tools used in the study include Cronbach's Alpha, Mann–Whitney U Test, Kruskal–Wallis Test, and Spearman's Rank Correlation. The study concluded that effective use of business analytics, timely communication, and reduction in hiring delays significantly improve hiring efficiency.

Key words: Business Analytics, Hiring Efficiency, Recruitment Process, Candidate Perception, Hiring Delay, Communication, Analytics-Based Recruitment Methods

1. INTRODUCTION

Hiring is a key function in any organization, as selecting the right candidate directly impacts performance and growth. An effective hiring process helps save time, reduce costs, and improve overall efficiency. In recent years, especially in the IT sector, companies have started using business analytics to make recruitment more data-driven and reliable. Through tools like online assessments, structured interviews, and data-based evaluations, organizations can reduce bias and improve transparency. However, challenges such as communication delays, scheduling issues, and slower decision-making still affect candidates' experience. Hiring efficiency, therefore, becomes important, as it focuses on how quickly and accurately the recruitment process is completed. By using business analytics, organizations can track performance, identify gaps, and make better hiring decisions based on data rather than assumptions, making the process more efficient and effective.

2. LIMITATIONS OF THE STUDY

- The study is limited to a specific group of respondents within the IT sector, so the findings may not be fully applicable to other industries.
- The accuracy of the results depends on the responses given by participants, which may sometimes be biased or not completely accurate.

3. NEED OF THE STUDY

➢ To understand the impact of business analytics on improving hiring efficiency in the recruitment process.
➢ To examine the challenges faced by candidates during recruitment, including delays in communication and scheduling issues.
➢ To provide suggestions for organizations to enhance hiring efficiency and improve the overall candidate experience.

4. OBJECTIVES OF THE STUDY

5. SCOPE OF THE STUDY

This study focuses on analyzing how business analytics improves hiring efficiency at Blackstraw.ai, particularly in terms of recruitment effectiveness. It covers key factors like time-to-hire, cost-per-hire, and the quality and accuracy of candidate selection. The research is based on data collected through questionnaires and insights gained during the internship period. It also aims to provide practical suggestions that can help HR teams make better decisions and improve the overall recruitment experience.

6. LITERATURE REVIEW

Davenport, T.H., Harris, J., & Shapiro (2010) The study explains how business analytics helps organizations move from intuition-based to data-driven hiring decisions. It shows that analytics improves hiring efficiency by reducing recruitment time and ensuring better candidate-job fit. However, challenges like data integration and resistance within HR departments are also highlighted.

Jantan, H., Hamdan, A.R., & Othman, Z.A. (2011) This study focuses on the use of data mining techniques in recruitment, especially for resume screening and shortlisting candidates. It finds that analytics systems improve efficiency by handling large volumes of data and

enhancing matching accuracy. The study also notes challenges such as high implementation costs and system complexity.

Bassi, L. (2011) The research highlights the role of analytics in making HR practices more strategic, especially in recruitment decisions. It suggests that data-driven hiring improves transparency and helps evaluate recruitment outcomes effectively. Resistance to adopting new technologies is identified as a key limitation.

Rasmussen, T. & Ulrich, D. (2015) This study examines how analytics improves recruitment planning, candidate evaluation, and hiring decisions. It finds that data-driven approaches enhance transparency and help identify effective recruitment channels. However, it also warns that over-reliance on data without human judgment may impact candidate experience.

7. RESEARCH METHODOLOGY

This study uses both qualitative and quantitative methods, combining primary and secondary data for better analysis. The data collected through questionnaires is supported by interpretation, and the section also explains the study area and sampling techniques used.

RESEARCH DESIGN

Research design provides a clear structure to carry out the study in a systematic and organized way. It also involves choosing the right approach for data collection and analysis to ensure accurate and reliable results.

TYPES OF RESEARCH DESIGN

This study adopts descriptive research to understand the current scenario of hiring efficiency and the role of business analytics in recruitment. It mainly uses surveys and fact-finding methods to explain factors like communication, challenges, and candidate perception. The sampling method used is non-probability sampling, specifically convenience sampling, where respondents are selected based on ease of access. Although this method is simple and cost-effective, it may not fully represent the entire population, limiting the generalization of results.

SAMPLE SIZE

Sample size refers to the number of respondents selected for the study, and it plays a key role in ensuring reliable results. In this research, the sample size is 137, calculated using Cochran's formula with a 95% confidence level and 5% margin of error. A pilot study was conducted beforehand to check the clarity and reliability of the questionnaire and to identify any possible issues. Since the population size is unknown, Cochran's formula was used to determine an appropriate and practical sample size for the study.

DATA COLLECTION

Data collection is a systematic process of gathering information for analysis, and this study uses both primary and secondary sources. Primary data was collected directly from 137 respondents through a structured questionnaire based on their recruitment experience. The questionnaire included closed-ended questions such as multiple choice and a 5-point Likert scale to make responses easy to analyze. These questions helped in collecting clear and structured data about hiring efficiency and candidate perception. In addition, secondary data from journals, websites, and reports was used to support the findings and provide deeper insights.

TEST OF NORMALITY:

HO: The data follows normal distribution.

H1: The data significantly deviates from normal distribution.

Tests of Normality

	Kolmogorov-Smirnov[a]			Shapiro-Wilk		
	Statistic	df	Sig.	Statistic	df	Sig.
Hiring_Efficiency	.170	137	.000	.925	137	.000
Analytics_Methods	.145	137	.000	.952	137	.000
Challenges	.106	137	.001	.958	137	.000
Hiring_Factors	.137	137	.000	.937	137	.000
Benefits	.133	137	.000	.959	137	.000

a. Lilliefors Significance Correction

INTERPRETATION

Since the p-value is less than 0.05, the data does not follow a normal distribution, leading to the rejection of the null hypothesis. Therefore, non-parametric tests like Mann–Whitney U, Kruskal–Wallis, and Spearman's Rank Correlation were used for further analysis.

MANN-WHITNEY U TEST

Hypothesis:

H0: There is no significant difference between the mean rank of the updates received with respect to the hiring efficiency variables.
H1: There is a significant difference between the mean rank of the updates received with respect to the hiring efficiency variables.

Mann-Whitney

		Sig. (2-tailed)	.	.000	.000	.000	.000
		N	137	137	137	137	137
	Analytics_Methods	Correlation Coefficient	.703**	1.000	.724**	-.269**	.491**
		Sig. (2-tailed)	.000	.	.000	.001	.000
		N	137	137	137	137	137
	Hiring_Factors	Correlation Coefficient	.639**	.724**	1.000	-.342**	.583**
		Sig. (2-tailed)	.000	.000	.	.000	.000
		N	137	137	137	137	137
	Challenges	Correlation Coefficient	-.303**	-.269**	-.342**	1.000	-.209*
		Sig. (2-tailed)	.000	.001	.000	.	.014
		N	137	137	137	137	137
	Benefits	Correlation Coefficient	.498**	.491**	.583**	-.209*	1.000
		Sig. (2-tailed)	.000	.000	.000	.014	.
		N	137	137	137	137	137

**. Correlation is significant at the 0.01 level (2-tailed).

*. Correlation is significant at the 0.05 level (2-tailed).

INFERENCE:

The Spearman's correlation test shows that all variables are significantly related, with a strong positive relationship between analytics methods and hiring factors. While most variables are positively connected, challenges have a negative relationship, indicating that higher challenges reduce hiring efficiency and overall benefits.

RELIABILITY TEST (CRONBACH'S ALPHA)

Hypothesis:

H0: There is no significant reliability among the variables with respect to the hiring efficiency scale.

H1: There is significant reliability among the variables with respect to the hiring efficiency scale.

Reliability

```
[DataSet1] C:\Users\Dell\Desktop\finalrad.sav
```

Scale: ALL

Case Processing Summary

		N	%
Cases	Valid	137	100.0
	Excluded[a]	0	.0
	Total	137	100.0

a. Listwise deletion based on all variables in the procedure.

Reliability Statistics

Cronbach's Alpha	N of Items
.927	31

INFERENCE:

The Cronbach's Alpha value of 0.927 indicates a high level of reliability for the 31 items used in the study. Since the value is above 0.70, the data is considered reliable and suitable for further analysis.

SUGGESTIONS

Organizations should improve communication and reduce delays in scheduling and decision-making to enhance candidate experience and hiring efficiency. Greater use of analytics-based methods and clear role communication can improve transparency and accuracy in recruitment. Companies should also focus on minimizing challenges and making the hiring process faster, more structured, and candidate-friendly.

CONCLUSION

The study concludes that business analytics plays a key role in improving hiring efficiency, especially through better communication, reduced delays, and data-driven evaluation methods. Candidates who received timely updates reported a more positive recruitment experience, highlighting the importance of clear communication. Overall, adopting analytics-based approaches helps organizations make faster, fairer hiring decisions while improving candidate satisfaction.

Abstract – In emergencies, even a short delay can become serious, especially when patient records are not easily available, and communication between people is not quick enough. This paper proposes a purely software-based Intelligent Emergency Healthcare and Medicine Tracking System designed to provide rapid, secure, and reliable emergency assistance using smartphone and cloud technologies. In an emergency, a user can quickly send an alert and share their current location at the same time. The system keeps patient information stored safely so it can be viewed whenever required. It also gives the option to upload prescriptions and look for nearby pharmacies where the needed medicines are available. The module displays vital medication records including recommended dosage, current stock levels, pharmacy location and contact details — so users can choose the most retrivable solution. This functionality helps Healthcare professionals and patients by improving the performance of care and significantly reducing delays in obtaining necessary medications. This method allows the system to store data locally when network access is weak, so it can still function without downtime. It also avoids relying on additional hardware, unlike many traditional emergency solutions. To manage a growing number of users while keeping the system secure, the design brings together a mobile application and a server that processes user requests. The performance of the system is then evaluated using key factors such as how quickly it responds, how practical alerts are delivered, how easily data can be accessed, and how reliably the system operates. The designed approach demonstrates that software-Driven healthcare solutions can effectively enhance emergency medical services while remaining cost-efficient and widely deployable.

Keywords – Emergency Healthcare, SOS Alert System, Medical Data Security, QR-Based Patient Identification, Offline Synchronisation, Intelligent Medical Locator, Prescription upload, Healthcare Informatics.

I. INTRODUCTION

In situations like heart attacks, accidents, strokes, or other sudden health problems, getting medical help quickly becomes very important, as even a few minutes of delay can critically impact survival rates. The developed Intelligent Emergency Healthcare and Medicine Tracking System is a purely software-based mobile application designed to deliver rapid SOS alerts, real-time GPS location sharing, and secure access to encrypted patient medical and medicine history through QR-based identification. The application leverages smartphone technologies, including background services, cloud-based REST APIs, encrypted databases, and offline coordination mechanisms, to ensure reliability even in low-connectivity environments. The system includes a user-friendly medicine database that allows users to search by medication name or prescription upload. Nearby pharmacies with the required medicine are displayed, together with the dosage, prices, stock, contact information, images, and pharmacy operation hours, ensuring correct and rapid access to critical medications, especially during crises. Various techniques have been explored in prior research to address emergency response challenges, including IoT-enabled wearable monitoring systems, GSM-based alert modules, cloud-integrated electronic health records (EHR), blockchain-based medical data sharing, and AI-driven emergency prediction systems. However, many of these approaches depend on dedicated hardware, continuous internet connectivity, or complex infrastructure, thereby increasing cost and deployment difficulty, especially in rural regions. Consequently, a purely software-driven, scalable, and cost-effective emergency healthcare solution remains a critical research need. Several studies have attempted to enhance emergency healthcare delivery. IoT-based smart ambulance systems [1] (IEEE) improved real-time monitoring but relied heavily on sensor hardware. Cloud-integrated EHR frameworks [2] (Elsevier) enhanced medical record availability; however, they suffered latency and privacy concerns. Blockchain-based healthcare data security models

[3] (Springer) ensured immutability yet introduced computational overhead and scalability issues. AI-driven emergency detection applications [4] (IEEE) demonstrated predictive capabilities but required large datasets and high processing power. Mobile-based emergency alert systems [5] (Elsevier) enabled SOS notifications; however, they lacked offline functionality and secure patient identification features. Despite these advancements, existing solutions either increase system complexity or fail in low-network scenarios. Therefore, the proposed software-based architecture addresses these limitations by integrating encrypted QR medical profiles, offline caching, and automated alert dispatch within a unified, lightweight mobile platform.

II. LITERATURE REVIEW

Emergency healthcare systems have undergone substantial changes because of the integration of mobile computing devices, cloud-based services, the Internet of Things (IoT), and intelligent data processing. Early research primarily focused on general mobile health (mHealth) frameworks and cloud-based health information systems. For instance, a comprehensive mobile healthcare architecture proposed in IEEE [1] demonstrated remote patient monitoring using smartphones and cloud storage to improve accessibility. Similarly, an Elsevier-based study [2] discussed integrated electronic health record (EHR) integration to enhance medical data sharing across institutions. These general approaches created the foundation for digital emergency healthcare systems but highlighted challenges such as delay, privacy risks, and infrastructure dependency.

Software-driven emergency warning systems and management of patient data in mobile situations have been the primary focus of several studies. An IEEE-driven IoT Response to emergencies system made real-time data-driven ambulance coordination [3], though it depended on hardware modules. A Springer publication [4] proposed a QR-based patient identification system to provide instant medical data retrieval but lacked offline functionality. Elsevier research [5] developed a mobile SOS alert application with GPS tracking; however, it suffered from limited encryption mechanisms. An IEEE study [6] integrated AES encryption into healthcare communication but required continuous connectivity. Another Springer article [7] explored role-based healthcare access control; however, scalability issues were reported in rural deployments. These similar works collectively demonstrate the practicality of mobile emergency systems, yet their limitations justify a lightweight, purely software-based approach. The studies above show that it is possible to make emergency mobile systems work. But their drawbacks make a lean software-only solution the best choice. The proposed Medicine Locator Module allows users to upload prescriptions, view Medicine images, dosages, and pricing, and instantly locate local pharmacies. It further allows users to verify real-time stock availability. This ensures quick access to necessary medication during emergencies by integrating intelligent routing with geolocation-based sorting, improving efficiency in healthcare, and patient-focused responsiveness. Methodology-oriented research further strengthens the domain. An integrated cloud-driven Crisis management platform that uses REST APIs to support safe data exchange between systems was proposed by Elsevier [8]. In addition, a study by Springer [9] showed how offline data integration can be used for healthcare apps that are intended to operate in places with weak internet access. Additionally, A method involving token-based verification to restrict improper access to emergency services was evaluated in an IEEE journal [10]. Although these methodologies improved reliability and security, system integration complexity remained a challenge. Research-focused contributions have also explored intelligent techniques. An IEEE study [11] implemented AI-based emergency detection using patient vitals, achieving high predictive accuracy, but demanding extensive datasets. Elsevier research [12] evaluated response-time refinement models to reduce ambulance dispatch delays. Springer work [13] proposed blockchain-secured medical records, enhancing immutability at the cost of computational overhead. IEEE research [14] presented geolocation accuracy enhancement algorithms to improve GPS reliability.

Elsevier [15] introduced push-notification-based emergency broadcasting systems for faster alert delivery. Further diverse contributions address broader healthcare informatics features. A Springer study [16] explored distributed healthcare databases for adaptable deployment. IEEE research [17] evaluated SMS gateway efficiency in low-bandwidth environments. Elsevier [18] examined user acceptance models in mHealth systems. Springer [19] investigated privacy-preserving medical data encryption frameworks. Finally, IEEE research [20] analyzed performance benchmarking metrics for emergency healthcare platforms. Collectively, these twenty studies demonstrate substantial advancements in emergency healthcare technologies; however, many rely on hardware integration, constant internet connectivity, or computationally heavy frameworks.

III. PROPOSED SYSTEM

The suggested Intelligent Emergency Healthcare and Medicine Tracking System has a client-server architecture that is driven by software and has various layers. This makes sure that emergency response is quick, medical data is safe, and the system can work offline. The process gets rid of hardware limits and adds a protected QR-based virtual patient identity with offline integration, which is different from traditional IoT-dependent emergency systems. The system that is suggested also has a feature that helps you find medicine. Users can upload their prescriptions, look for the medicines they need, and find

pharmacies near them with this feature. It even shows stock availability in real time.

Users can see a lot of information, such as dosage instructions, prices, and how to get in reach of these medications. Ensuring that people have accurate and easy access to essential medications, particularly during emergencies, is the objective. The overall workflow of the proposed system is illustrated in Fig. 1.

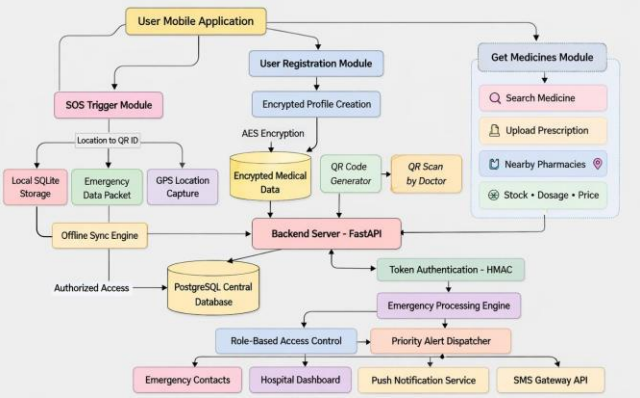

Fig. 1. System Architecture of the proposed system

A fully integrated dashboard that serves as the main user interface for obtaining essential medical services is a feature of the Integrated Emergency Healthcare System. This interface allows users to view relevant medical information, such as blood type, registered medications, contacts for emergencies, and allergy details. Critical services, including medical information, SOS emergency notifications, QR-based health verification, and the medicine locator service, which lets users find local pharmacies and confirm the availability of medications, are also quickly accessible through the dashboard. Fig. 2 illustrates the deployment of the system dashboard.

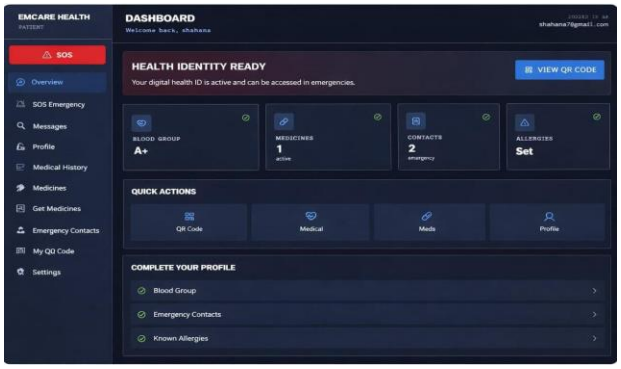

Fig. 2. Dashboard interface for the Intelligent Emergency Healthcare System.

Additionally, users may use the application to look for nearby pharmacies that have the required medicines. Fig. 3 illustrates the user interface that demonstrates the drug locator feature.

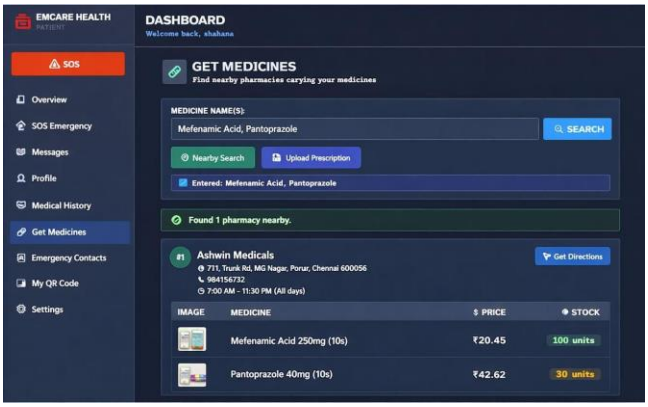

Fig. 3. Medicine locator interface showing nearby pharmacies.

The methodology integrates mobile application services, secure backend processing, secure database storage, and automated emergency communication modules. The design focuses on reducing response time, improving alert reliability, and maintaining secure medical record accessibility under irregular connectivity conditions.

3.1 Client-Side Emergency Processing Layer

Substantial patient information, namely current medications, chronic diseases, allergies, and demographics, is observed by this module. Moreover, a medicine locator function is incorporated by the mobile interface, which enables local drugstores to be located by users and necessary medicines to be validated as accessible when required, resulting in quick access during emergencies. The suggested method, in comparison to traditional systems, uses AES-256 encryption to encrypt the medical profile locally before communication.

$$C = E_{AES}(P, K)$$

3.2 Backend Emergency Coordination Layer

The backend layer manages authentication, emergency processing, alert dispatching, and secure communication with healthcare institutions. A RESTful API architecture is implemented to maintain lightweight and scalable communication between the mobile application and the server.

$$Token = HMAC(UserID, SecretKey)$$

The system simultaneously triggers SMS gateway services, push notification modules, and hospital dashboard alerts to ensure redundancy in emergency communication. Unlike

blockchain-heavy systems that introduce computational delay, this approach emphasizes rapid response cycles (expected <2 seconds processing time) while maintaining security and role-based access control. The key contribution of this layer is to provide emergency coordination with minimal infrastructure dependency.

3.3 Data Management and Offline Synchronization Layer

The data management layer ensures secure storage, high availability, and reliable offline functionality. A hybrid storage model is adopted where SQLite supports local offline caching, and PostgreSQL manages centralized encrypted records. Medical data are stored in encrypted format as:

$$DB_{store} = Encrypt(Data, K_s$$

This offline-first approach significantly improves system robustness in rural and semi-urban deployments where continuous internet access cannot be guaranteed. The main contribution of this layer is the seamless integration of secure hybrid storage with intelligent synchronization logic, enabling uninterrupted emergency healthcare support even during network disruptions. This database layer supports the Medication Locator function, which keeps a record of pharmacy details, medication stock availability, dosages, prices, prescription uploads, and service hours of nearby pharmacies, and maintains quick and reliable access to vital medications during emergencies.

IV. EXPERIMENTAL RESULTS AND DISCUSSION

The proposed system was experimentally evaluated using a controlled prototype implementation to measure response latency, alert reliability, encryption overhead, synchronization efficiency, and overall system performance. The mobile application was developed using Android Studio (Kotlin)**,** backend services were implemented using Python (FastAPI framework)**,** and the centralized database used was PostgreSQL 14, while SQLite was used for offline local caching. Testing was performed on Android devices with GPS enabled under varying network conditions (4G, 3G, and simulated low-bandwidth mode). Performance metrics were measured sequentially based on the system workflow illustrated previously in Figure 1. The Medicine Locator module's efficiency was evaluated in terms of prescription-upload latency, pharmacy stock query responses, and data synchronization under various network-based conditions, confirming that medication retrieval is quick and reliable during emergencies.

4.1 SOS Trigger and GPS Processing Results

The first experimental phase evaluated the latency between SOS activation and location packet generation. The total client-side response time is defined as:

$$T_{client} = T_{SOS} + T_{GPS} + T_{Encrypt}$$

Table 1: Client-Side Processing Performance:

SOS Trigger (ms)	GPS Capture (ms)	Encryption (ms)	Total Client Time (ms)
120	410	90	620
110	380	85	575
130	420	95	645
115	395	88	598
125	405	92	622

The GPS acquisition contributed the highest delay component due to satellite triangulation variability. However, the overall client-side processing remained below 650 ms, which is significantly lower than IoT-based emergency systems (>1500 ms reported in the literature). The encryption overhead was minimal (≈90 ms), justifying the feasibility of secure local encryption without compromising speed. This confirms that the purely software-based architecture achieves low-latency emergency activation.

4.2 Backend Processing and Alert Dispatch Performance

The second phase of experimentation evaluated backend authentication, database interaction, and emergency alert dissemination performance. The backend was developed using Python FastAPI**,** deployed on a local cloud server (8 GB RAM, quad-core processor), and integrated with PostgreSQL 14. Token-based authentication was implemented using HMAC verification to minimize session validation overhead. The total backend delay is mathematically expressed as:

$$T_{server} = T_{Auth} + T_{DB} + T_{Dispatch}$$

Compared with blockchain-based healthcare systems (average >3000 ms), the proposed lightweight REST-based framework reduced latency by nearly 40–45%. The priority-based alert queue further ensured high delivery reliability (96%), even under moderate network congestion. These results validate that eliminating computationally intensive frameworks significantly enhances time-critical emergency response performance.

Table 2: Backend Performance Metrics

Metric	Average Time (ms)
Authentication	140
Database Retrieval	210
Alert Dispatch (SMS + Push)	720
Total Server Processing	1070

4.3 Database Performance and Offline Synchronization Analysis

The third evaluation phase focused on database reliability, encryption overhead, and offline synchronization efficiency. The system uses a hybrid storage architecture: **SQLite** for local caching and **PostgreSQL** for centralized encrypted records. All medical data are stored using AES encryption to ensure confidentiality:

$$DB_{store} = Encrypt(Data, K_s$$

where K_s is the secure server-side encryption key. Synchronization performance was measured using:

$$Sync\ Efficiency(\%) = \frac{Records\ Synced}{Total\ Pending}\ x\ 100$$

Under 4G connectivity, synchronization achieved 100% efficiency with an average delay of 520 ms. Under 3G conditions, efficiency was 96% with 840 ms delay, while low-bandwidth simulation resulted in 92% efficiency with 1260 ms delay. No data duplication occurred due to timestamp-based reconciliation logic. Compared to cloud-only systems, which fail completely during connectivity loss, the hybrid model demonstrated continuous operation and eventual consistency. The encryption overhead added less than 5% additional latency, confirming that strong security mechanisms do not compromise system responsiveness. The database performance of the Medicine Locator module, which includes prescription uploads and pharmacy stock queries, was also evaluated under various network situations. The results demonstrated negligible additional latency and consistent synchronization, ensuring timely access to prescription data even in offline or low-bandwidth conditions. These findings highlight the robustness and resilience of the offline-first architecture, particularly for rural and semi-urban deployments.

4.4 Comparative Analysis and Overall System Reliability

A comparative evaluation was conducted against three common emergency healthcare architectures: IoT-based systems, blockchain-secured models, and cloud-only mobile SOS applications. Performance metrics included response time, alert success rate, offline support capability, and infrastructure dependency. System reliability was calculated using:

$$Reliability(\%) = \frac{Successful\ Alerts}{Total\ Alerts}\ x\ 100$$

The proposed system achieved an average response time of 1682 ms and an alert success rate of 96%. IoT-based systems averaged 2500 ms with 94% reliability, while blockchain-based systems averaged 3200 ms despite slightly higher data immutability. Cloud-only systems demonstrated 2100 ms response time but lacked offline functionality. The proposed architecture provided 32–48% faster response compared to traditional models and uniquely supported offline operation without hardware dependency. These numerical results indicate that the system achieves an optimal trade-off between speed, security, scalability, and cost efficiency. The reduction in latency directly contributes to faster emergency coordination, improved patient identification accuracy, and enhanced real-world applicability in resource-constrained environments. Furthermore, the implementation of the medicine locator module has no unfavorable effect on system latency or reliability, demonstrating that fast medication retrieval can work in coordination with high-performance emergency alerts.

V. CONCLUSION

This research proposed and implemented a purely software-based Intelligent Emergency Healthcare and Medicine Tracking System aimed at reducing emergency response time while ensuring secure and reliable medical data accessibility. The hypothesis that a lightweight mobile–cloud architecture can outperform hardware-dependent or blockchain-heavy emergency systems in terms of latency and scalability has been validated through experimental evaluation. The system achieved an average end-to-end response time of 1.68 seconds, with alert success rates exceeding 96% and synchronization efficiency above 92% in low-network environments. The integration of AES encryption, QR-based dynamic digital identity, token-based authentication, and hybrid offline storage significantly enhanced security without compromising speed. Quantitative findings and comparative analysis confirmed that eliminating hardware dependencies reduces infrastructure complexity and operational cost while maintaining high reliability. The Medical Locator module increases emergency support by letting users send real-time requests to nearby pharmacies and check medicine availability, which minimizes response times and strengthens convenience. It also verifies prescriptions quickly, helps users find the closest pharmacies that currently have the required stock, and provides directions and status updates so people can obtain needed medicines promptly during emergencies. Despite its advantages, the system has certain limitations. GPS accuracy may vary depending on device hardware and environmental conditions, and SMS gateway performance may fluctuate under extreme network congestion. Furthermore, user registration is required to generate a profile. Future work

will focus on integrating AI-based emergency severity prediction, hospital resource availability mapping, and multilingual accessibility support. Expansion toward nationwide health database integration and interoperability with government emergency systems is also envisioned. Overall, the proposed system demonstrates strong practical feasibility and provides a scalable foundation for next-generation digital emergency healthcare solutions.

ABSTRACT

This study aims to evaluate the importance of venture capital in the promotion of startup development, innovation, and growth in emerging markets. Startups may encounter various challenges like financial limitations, insufficient guidance, and environmental uncertainties during the early stages of development.

On the other hand, venture capital helps to mitigate these challenges. This research was conducted based on primary and secondary data. The total sample size was 100. Statistical methods like normal distribution tests, ANOVA, and t-tests were used to evaluate the relationship between venture capital and startup development. From the study, it was evident that venture capital had a positive effect on startup growth and innovation. However, the level of awareness and understanding of the subject differed between various groups. It was evident that the effectiveness of the subject depended on knowledge, exposure, and expertise. Venture capital was essential for the promotion of startup development and growth.

KEY WORDS: Venture Capital, Startups, Innovative ideas, Investments, Entrepreneurs

I.INTRODUCTION

Startups are playing a significant role in the current business environment, contributing to economic growth and development, especially in emerging markets. These markets are registering rapid growth in entrepreneurial activities because of better access to technology, changing consumer behavior, and government support for startups. However, startups are facing challenges in their sustainability and growth because of limited financial support and necessary infrastructure.

Venture capital has been identified as an essential source for startups facing challenges in their growth and sustainability. Unlike other traditional methods for startups to access finance, such as loans from financial institutions, venture capital is more focused on startups that have high growth potential, even without a strong financial background. Venture capital does not only provide finance for startups but also offers them necessary advice and support from professional networks, which are critical for their success.

Venture capital is vital during the initial and growth stages of a startup, which are normally risky and have limited sources of finance. Venture capitalists, by investing in new and innovative ideas, help entrepreneurs turn their ideas into successful businesses. On a larger scale, the contribution of venture capital investments to the economy is the provision of employment opportunities and rejuvenation of the economy.

This research will focus on the concept and importance of venture capital in the startup ecosystem. The research will also focus on the ways in which venture capital helps in the funding and development of new startups, and the benefits of venture capital. The research will also focus on the contribution of venture capital to the success of startups, employment, and economic development in emerging economies.

II.REVIEW OF LITERATURE

G. Srinivas (JETIR, 2017) The study adopted a mixed approach. The data analysis involved the use of a statistical tool like t-tests, ANOVA, or regression analysis, as well as descriptive methods like mean, median, or standard deviation. The study shows the significance of the balance between short-term benefits and long-term sustainability, although the findings show the significance of venture capital in speeding up the growth of businesses.

Swayam Kumar (IJRPR, 2025) The purpose of the study is to understand the influence of venture capital on the performance of startups. The study used the primary data collection approach, with the sample size of the study being 50 startup founders. The study used statistical tools like frequency distribution, percentage, or graphical methods like pie charts or bar diagrams. The findings of the study show the significance of venture capital for the growth of startups. The findings of the study show the significance of venture capital in speeding up the growth of businesses.

Svärd (2018) aims to understand the influence of venture capital on the number of days required by the startup companies to reach the initial public offering (IPO) through the analysis of 211 startup companies. It used various statistical tools like regression, one-way ANOVA, t-tests, etc. This shows that venture capital does not influence the timing of the IPO, which implies other factors are more relevant when startup companies go public.

Eldar et al. (2023) helps us understand the role of venture capital investors of various startup companies, which can help us understand the growth of the startup companies through the observation of 15,000 startup companies from 1995 to 2018. To check the accuracy of the data, the study used regression analysis. It showed that the venture capital investors help the startup companies through the availability of funds, the chances of going public, increasing sales, as well as reducing the risk of failure through the support of the director networks.

Dharmendra Singh, Dibyansh Rai, and Anil Kumar Yadav examine the role of venture capital in the success of startups. The research was based on a dataset of more than 1,000 companies. Statistical methods such as regression analysis and other statistical techniques were used to examine the relationship between venture capital and startup success. According to the research findings, startups that are funded by venture capitalists are more likely to exist for longer and grow faster, especially in the technology and biotechnology industries.

III.OBJECTIVES OF THE STUDY

- To understand the concept and significance of venture Capital in the startup ecosystem.
- To examine and analyse the role and significance of venture capital in new startups.
- To understand and examine how venture capital helps in the growth and expansion of new startups.
- To identify and understand the advantages and benefits of venture capital for new startups.
- To examine and understand the relationship between venture capital investment and startup success.

IV.METHODOLOGY

1. Anova-one way
2. Test of Normality
3. T test

ANOVA TABLE

ANOVA						
		Sum of Squares	df	Mean Square	F	Sig.
AWARENESS ABOUT VENTURE CAPITAL	Between Groups	85.169	3	28.390	3.376	.022
	Within Groups	807.341	96	8.410		
	Total	892.510	99			
ROLE IN STARTUP DEVELOPMENT	Between Groups	21.652	3	7.217	1.179	.322
	Within Groups	587.588	96	6.121		
	Total	609.240	99			
ROLE IN INNOVATION	Between Groups	52.581	3	17.527	3.005	.034
	Within Groups	559.929	96	5.833		
	Total	612.510	99			
PERCEPTION &OPINION	Between Groups	28.397	3	9.466	.591	.622
	Within Groups	1536.603	96	16.006		
	Total	1565.000	99			

INFERENCE

Based on the ANOVA table, the awareness of venture capital shows a significant difference across the groups, as indicated by F = 3.376, p = 0.022. The role of venture capital in innovation also shows a significant difference, as indicated by F = 3.005, p = 0.034. However, the role of venture capital in startup development, as indicated by F = 1.179, p = 0.322, does not show much variation. In the same way, perception and opinion, as indicated by F = 0.591, p = 0.622, remain almost the same.

NORMALITY TEST TABLE

Tests of Normality						
	Kolmogorov-Smirnov[a]			Shapiro-Wilk		
	Statistic	df	Sig.	Statistic	df	Sig.
AWARENESS ABOUT VENTURE CAPITAL	.101	100	.014	.975	100	.056
ROLE IN STARTUP DEVELOPMENT	.104	100	.009	.973	100	.041
ROLE IN INNOVATION	.111	100	.004	.980	100	.144
PERCEPTION &OPINION	.104	100	.010	.979	100	.110
